Moscow ML Library Documentation

rsion 2.00 of June 2000

Sergei Romanenko, Russian Academy of Sciences, Moscow, Russia Claudio Russo, Cambridge University, Cambridge, United Kingdom Peter Sestoft, Royal Veterinary and Agricultural University, Copenhagen, Denmark

This document

This manual describes the Moscow ML library, which includes parts of the SML Basis Library and several extensions. The manual has been generated automatically from the commented signature files.

Alternative formats of this document

Hypertext on the World-Wide Web

The manual is available at http://www.dina.kvl.dk/~sestoft/mosmllib/ for online browsing.

Hypertext in the Moscow ML distribution

The manual is available for offline browsing at mosml/doc/mosmllib/index.html in the distribution.

On-line help in the Moscow ML interactive system

The manual is available also in interactive mosml sessions. Type help "lib"; for an overview of built-in function libraries. Type help "fromString. This will produce a menu of all library structures which contain the identifier fromstring (disregarding the lowercase/uppercase distinction):

			_	_	_	_	_
Bool.fromString Char.fromString	Date.fromString	int.iromstring Path.fromString	Real.fromString	String.fromString	Time.fromString	Word.fromString	Word8.fromString
val	val	val	val	val	val	val	val
7 7	ω •	4 10	9	7	∞	9	10

Choosing a number from this menu will invoke the help browser on the desired structure, e.g. Int.

The Moscow ML home page is http://www.dina.kvl.dk/~sestoft/mosml.html

APPLESCRIPT 2

Module AppleScript

```
AppleScript -- Apple MacOS scripting
```

type OSAID type OSAerr = int

exception AppleScriptErr of OSAerr * string

as_compile : string -> OSALD as_dispose : OSALD -> unit as_run_script : OSALD -> string as_run_text : string -> string val val

These Mac specific functions provide the capability to compile and run AppleScript programs. The exception AppleScriptErr is raised in the event of an error.

[as compile str] compiles AppleScript source code text, returning an abstract token of type OSAID. This token may be used to run the script. The token may be used repeatedly until it is returned with as_dispose or until mosml exits. [as dispose tok] disposes of the resources associated with the OSAID token so that they may be reused by the AppleScript system. AppleScriptErr is raised upon any attemp to reuse a disposed token.

[as_run_script tok] runs the script associated with the token. This typically involves AppleBvent communication with other programs running on the Mac, or networked Macs. The AppleScript result is returned as a string.

[as_run_text str] compiles and runs the AppleScript source code text, disposing all resources allocated in the process, and returns the AppleScript result as a string.

['ty array] is the type of one-dimensional, mutable, zero-based constant-time-access arrays with elements of type 'ty. Type 'ty array admits equality even if 'ty does not. Arrays al and az are equal if both were created by the same call to a primitive (array, tabulate, fromList).

Functions working on a slices (contiguous subsequence) of an array are found in the ArraySlice structure.

[maxLen] is the maximal number of elements in an array.

[array(n, x)] returns a new array of length n whose elements are all x. Raises Size if n<0 or n>maxLen.

[tabulate(n, f)] returns a new array of length n whose elements are f 0, f 1, ..., f (n-1), created from left to right. Raises Size if n<0 or n>maxLen.

XS. [fromList xs] returns an array whose elements are those of Raises Size if length xs > maxLen.

[length a] returns the number of elements in

use [sub(a, i)] returns the i'th element of a, counting from 0. Raises Subscript if i<0 or i>=length a. To make 'sub' infix, the declaration

infix 9 sub

[update(a, i, x)] destructively replaces the i'th element of a by x. Raises Subscript if i<0 or i>=length a.

[copy{src, dst, di}] destructively copies the array src to dst, starting at index di.
Raises Subscript if di<0, or if di + length src > length dst.

4

[copyyec{src, dst, di}] destructively copies the vector to dst, starting at index di.
Raises Subscript if di<0, or if di + Vector.length src > length dst.

[find p a] applies p to each element x of a, from left to right, until p(x) evaluates to true; returns ${\rm SOME}$ x if such an x exists, otherwise NONE

[exists p a] applies p to each element x of a, from left to right, until p(x) evaluates to true; returns true if such an x exists, otherwise false.

[all p al applies p to each element x of a, from left to right, until p(x) evaluates to false; returns false if such an x exists, otherwise true.

That is, [fold] f e a] folds function f over a from left to right. That i computes f(a[len-1], f(a[len-2], ..., f(a[l], f(a[0], e)) ...)), where len is the length of a.

That is, ...)), [foldr f e a] folds function f over a from right to left. computes f(a[0], f(a[1], ..., f(a[len-2], f(a[len-1], e)) where len is the length of a.

[app f a] applies f to a[j] for j=0,1,...,length a-1.

[modify f a] applies f to a[j] and updates a[j] with the result f(a[j]) for j=0,1,...,length a-1.

The following iterators generalize the above ones by passing also the index j to the function being iterated.

[findi p a] applies f to successive pairs (j, a[j]) for $j=0,1,\ldots,n-1$, until p(j, a[j]) evaluates to true; returns SOME (j, a[j]) if such a pair exists, otherwise NONE.

[foldli f e a] folds function f over the array from left to right. That is, computes f(n-1, a[n-1], f(..., f(1, a[1], f(0, a[0], e)) ...)).

[foldri f e a] folds function f over the array from right to left. That is, computes f(0, a[0], f(1, a[1], ..., f(n-1, a[n-1], e) ...)).

[appi f a] applies f to successive pairs (j, a[j]) for j=0,1,...,n-1.

[modifyi f a] applies f to (j, a[j]) and updates a[j] with the result f(j, a[j]) for j=0,1,...,n-1.

[collate cmp (xs, ys)] returns LESS, EQUAL or GREATER according as xs precedes, equals or follows ys in the lexicographic ordering on arrays induced by the ordering cmp on elements.

Module Array2

['ty array] is the type of two-dimensional, mutable, zero-based constant-time-access arrays with elements of type 'ty.

Type 'ty array admits equality even if 'ty does not. Arrays al and a2 are equal if both were created by the same call to one of the primitives array, fromList, and tabulate.

[traversal] is the type of traversal orders: row major or column major.

[RowMajor] specifies that an operation must be done in row-major order, that is, one row at a time, from top to bottom, and from left to right within each row. Row-major traversal visits the elements of an (m,n)-array with m rows and n columns in this order:

(0,0), (0,1), (0,2), ..., (0,n-1), (1,0), (1,1), (1,2), ..., (1,n-1),

that is, in order of lexicographically increasing (i, j). In Moscow ML, row-major traversal is usually faster than column-major

[ColMajor] specifies that an operation must be done in column-major order, that is, one column at a time, from left to right, and from top to bottom within each column. Column-major traversal visits the elements of an (m.n)-array with m rows and n columns in this

that is, in order of lexicographically increasing (j, i).

[array(m, n, x)] returns a new m * n matrix whose Raises Size if n<0 or m<0.

[fromList xss] returns a new array whose first row has elements

9

xs1, second row has elements xs2, ..., where xss = [xs1,xs2,...,xsm] Raises Size if the lists in xss do not all have the same length.

[tabulate RowMajor (m, n, f)] returns a new m-by-n array whose elements are f(0,0), f(0,1), ..., f(0, n-1), f(1,0), f(1,1), ..., f(1, n-1),

created in row-major order: f(0,0), f(0,1), ..., f(1,0), f(1,1), Raises Size if nc0 or m<0.

[tabulate ColMajor (m, n, f)] returns a new m-by-n array whose elements are as above, but created in the column-major order: f(0,0), f(1,0), ..., f(0,1), f(1,1), ... Raises Size if n<0 or m<0.

[dimensions a] returns the dimensions (m, n) of a, where m is the number of rows and n the number of columns.

ъ nCols a] returns the number of n of columns of

[nRows a] returns the number of m of rows of a.

[sub(a, i, j)] returns the i'th row's j'th element, counting from 0. Raises Subscript if i<0 or j<0 or i>=m or j>=n where (m,n) = dimensions a.

οĘ [update(a, i, j, x)] destructively replaces the (i,j)'th element by x. Raises Subscript if i<0 or j<0 or i>=m or j>=n where (m,n) = dimensions a.

[row (a, i)] returns a vector containing the elements of the ith row of a. Raises Subscript if i < 0 or i >= height a.

[column (a, j)] returns a vector containing the elements of the jth

Raises Subscript if j < 0 or j >= width a. column of a.

[app RowMajor f a] applies f to the elements a[0,0], a[0,1], ..., a[0,n-1], a[1,0], ..., a[m-1, n-1] of a, where (m, n) = dimensions

[app ColMajor f a] applies f to the elements a[0,0], a[1,0], ..., a[m-1,0], a[0,1], a[1,1], ..., a[m-1, n-1] of a, where (m, n) = dimensions a. [modify RowMajor f a] applies f to the elements a[0,0], a[0,1], ..., a[0,n-1], a[1,0], ..., a[m-1, n-1] of a, updating each element with the result of the application, where $(m,\ n)$ = dimensions a. [modify ColMajor f a] applies f to the elements a[0,0], a[1,0], ..., a[m-1,0], a[0,1], a[1,1], ..., a[m-1, n-1] of a, updating element with the result of the application, where $(\mathfrak{m},\,\mathfrak{n})$ = dimensions a

each

[fold RowMajor f b a] folds f left-right and top-down over the elements of a in row-major order. That is, computes fa[m-1, n-1], f(a[m-1, n-2], ..., f(a[0,1], f(a[0,0], b)) where (m, n) = dimensions a.

[fold ColMajor f b a] folds f left-right and top-down over the elements of a in column-major order. That is, computes f(a[m-1, n-1], f(a[m-2, n-1], ..., f(a[1,0], f(a[0,0], b)) where (m, n) = dimensions a.

The following iterators generalize the above ones in two ways:

* the indexes i and j are also being passed to the function: * the iterators work on a region (submatrix) of a matrix.

[region] is the type of records { base, row, col, nrows, ncols } determining the region or submatrix of array base whose upper left corner has index (row, col).

ARRAY2

If nrows = SOME r, then the region has r rows: row, row+t, ..., row+r If nrows = NONE, then the region extends to the bottom of the matrix. The field ncols similarly determines the number of columns.

A region is valid for an array with dimensions (m, n) if (1) either arrows = NONE and 0 = row <= m or arrows = SOME r and 0 <= row <= row + r <= m and (2) either neols = NONE and 0 <= col <= n

or ncols = SOME c and $0 \le col \le col + c \le n$.

[appi RowMajor f reg] applies f to (i, j, a[i, j]) in order of lexicographically increasing (i, j) within the region reg. Raises Subscript if reg is not valid. Note that app tr f a is equivalent to appi tr (f reg is not leaved. Note that app rr f or sequivalent to appi tr (f o #3) {base=a, row=0, col=0, mrows=NONE, ncols=NONE}

of Raises [appi ColMajor f reg] applies f to (i, j, a[i, j]) in order lexicographically increasing (j, i) within the region reg. Subscript if reg is not valid. [modifyi RowMajor f reg)] applies f to (i, j, ali, j]) in order of extrographically increasing (i, j) within the region reg. Raises Subscript if reg is not valid. Note that modify tr f a is equivalent to modifyi (f o #3) {base=a, row=0, col=0, nrows=NONE, ncols=NONE}).

[modifyi ColMajor f reg)] applies f to (i, j, a[i, j]) in order of lexicographically increasing (j, i) within the region reg. Raises Subscript if reg is not valid.

[foldi RowMajor f b a] folds f over (i, j, a[i, j]) in row-major order within the region reg, that is, for lexicographically increasing (i, j) in the region. Raises Subscript if reg is not valid. [foldi ColMajor f b a] folds f over (i, j, a[i, j]) in column-major order within the region reg, that is, for lexicographically increasing (j, i) in the region. Raises Subscript if reg is not

[copy { src, dst, dst_row, dst_col }] copies the region determined by src to array dst such that the upper leftmost corner of src is copied to dst[dst_row, dst_col]. Works correctly even when src and dst are the same and the source and destination regions overlap. Raises Subscript if the src region is invalid, or if src translated to (dst_row, dst_col) is invalid for dst.

ARRAYSLICE

```

['ty slice] is the type of array slices, that is, sub-arrays. The slice (a,i,n) is valid if 0 <= i <= i+n <= size s, or equivalently, 0 <= i and 0 <= n and i+n <= size s.
A valid slice sli = (a,i,n) represents the sub-array a[i...i+n-1], so the elements of sli are a[i], ali+l], ..., ali+n-1, and n is the length of the slice. Only valid slices can be constructed by

functions below. so tl the the

[length sli] returns the number n of elements in sli = (s,i,n)

[sub (sli, k)] returns the k'th element of the slice, that is, a(i+k) where sli = (a,i,n). Raises Subscript if k<0 or k>=n. a(i+k) where sli = (a,i,n). [update (sli, k, x)] destructively replaces the k'th element of sli by x. That is, replaces a(k+i) by x, where sli = (a,i,n). Raises Subscript if i<0 or i>=n.

[slice (a, i, NONE)] creates the slice (a, i, length a-i), consisting of the tail of a starting at i. Raises Subscriber If is (or i > Array.length a. Equivalent to slice (a, i, SOME(Array.length a - i)).

[slice (a, i, SOME n)] creates the slice (a, i, n), consisting of the sub-array of a with length n starting at i. Raises Subscript if i<0 or n<0 or i+n > Array.length a.

	a[0len-1	ix) a[0n-1]	fix) a[ilen-1]	a[ii+n-1]
meaning	the whole array	a left sub-array (pref:	a right sub-array (suf	a general slice
slice	a, 0,	(a, 0, SOME n)	(a, i, NONE)	(a, i, SOME n)

[full a] creates the slice (a, 0, length a).

ARRAYSLICE

```
Equivalent to slice(a,0,NONE
```

```
[subslice (sli, i', NONE)] returns the slice (a, i+i', n-i') when sli = (a,i,n). Raises Subscript if i' < 0 or i' > n.
```

[subslice (sli, i', SOME n')] returns the slice (a, i+i', n') when sli = (a,i,n). Raises Subscript if i' < 0 or n' < 0 or i'+n' > n.

[base sli] is the concrete triple (a, i, n) when sli = (a, i, n).

[vector sli] oreates and returns a vector consisting of the elements of the slice, that is, a[i..i+n-1] when sli = (a,i,n).

[copy {src, dst, di}] copies the elements of slice src = (a,i,n), that is, ail.i.m-1]. To the destination segment dst[di.-di+n-1]. Raises Subscript if di<0 or if di+n > length dst. Works also if the array underlying sli is the same as dst, and the slice overlaps with the destination segment.

[copyvec {src, dst, di}] copies the elements of the vector slice src = (v,i,n), that is, v(i...i+n-1], to dst[di..di+n-1]. Raises Subscript if di<0, or if len=NONE and di + n > length dst.

[isEmpty sli] returns true if the slice sli = (a,i,n) is empty, that is, if n=0.

and getItem sli] returns SOME(x, rst) where x is the first element are the remainder of sli, if sli is non-empty; otherwise returns

[find p sli] applies p to each element x of sli, from left to right, until p(x) evaluates to true; returns SOME x if such an x exists, otherwise NONE.

from left to right [exists p sli] applies p to each element x of sli, from left to until p(x) evaluates to true; returns true if such an x exists, otherwise false.

from left to right, such an x exists, [all p sli] applies p to each element x of sli, until p(x) evaluates to false; returns false if otherwise true.

[app f sli] applies f to all elements of sli = (a,i,n), from left to right. That is, applies f to a[j+i] for j=0,1,...,n.

[fold] f e sli] folds function f over sli = (a,i,n) from left to right. That is, computes f(a[i+n-1], f(a[i+n-2],..., f(a[i+1], f(a[i], e))...)).

[foldr f e sli] folds function f over sli = (a,i,n) from right to left. That is, computes f(a[i]), f(a[i+1]),..., f(a[i+n-2]), f(a[i+n-1]), e))...)).

[modify f sli] modifies the elements of the slice sli = (a,i,n) by function f. That is, applies f to a[i+j] and updates a[i+j] with the result f(a[i+j]) for j=0,1,...,n.

The following iterators generalize the above ones by also passing the index into the array a underlying the slice to the function the index into the being iterated. [findi p sli] applies p to the elements of sli = (a,i,n) and the underlying array indices, and returns the least (j,a[i]) for which (j,a[i]) evaluates to true, if any otherwise returns NONE. That is, evaluates p(j,a[i]) for j=i,...+n-1 until it evaluates to true for some j, then returns SOME(j,a[i]); otherwise returns NONE.

[appi f sli] applies f to the slice sli = (a,i,n) and the underlying array indices. That is, applies f to successive pairs (j, a[j]) for j=i,i+1,...,i+n-1.

[foldli f e sli] folds function f over the slice sli = (a,i,n) and the underlying array indices from left to right. That is, computes $f(i+n-1, a[i+n-1], f(\dots, f(i+1, a[i+1], f(i, a[i], e)) \dots))$.

ARRAYSLICE 10

[foldri f e sli] folds function f over the slice sli = (a,i,n) and the underlying array indices from right to left. That is, computes f(i, a[i], f(i+1, a[i+1], ..., f(i+n-1, a[i+n-1], e) ...)).

[modifyi f sli] modifies the elements of the slice sli = (a,i,n) by applying function f to the slice elements and the underlying array indices. That is, applies f to (i,a[i]) and updates a[j] with the result f(j,a[j]) for $j=i,i+1,\ldots,i+n-1$.

[collate cmp (sli1, sli2)] returns LESS, EQUAL or GREATER according as sli1 precedes, equals or follows sli2 in the lexicographic ordering on slices induced by the ordering cmp on elements.

ARRAYSORT

Module Arraysort

Arraysort -- Quicksort for arrays, from SML/NJ library

val sort : ('a * 'a -> order) -> 'a Array.array -> unit
val sorted : ('a * 'a -> order) -> 'a Array.array -> bool

[sort ordr arr] sorts array arr in-place, using ordering relation ordr.

[sorted ordr arr] returns true if the elements of array arr is appear in (weakly) increasing order, according to ordering ordr.

BINIO 12

Module BinIO

```
BinIO -- SML Basis Library
```

type elem = Word8.word type vector = Word8Vector.vector

Binary input

type instream

: instream -> vector
instream -> vector
k : instream -> vector option
: instream -> elem option
: instream * int -> vector
: instream *> bool
: instream -> elem option
: instream -> elem option instream -> unit ^ string inputAll inputNoBlock: input1 inputN endOfStream: lookahead openIn closeIn input val val val val val val val

Binary output

type outstream

outstream -> unit
outstream * vector -> unit
outstream * elem -> unit : string -> outstream : string -> outstream openAppend closeOut open0ut val val val

output output1 flushOut

-> unit

This structure provides input/output functions on byte streams. The functions are state-based: reading from or writing to a stream changes the state of the stream. The streams are buffered: output to a stream may not immediately affect the underlying file or device.

[instream] is the type of state-based byte input streams.

[outstream] is the type of state-based byte output streams

[elem] is the type Word8.word of bytes

[vector] is the type of Word8Vector.vector (byte vectors).

BYTE INPUT:

ω. file named [openIn s] creates a new instream associated with the file Raises Io.Io is file s does not exist or is not accessible. [closeIn istr] closes stream istr. Has no effect if istr is closed already. Further operations on istr will behave as if istr is at end of stream (that is, will return "" or NONE or true).

[input istr] reads some elements from istr, returning a vector v of those elements. The vector will be empty (size v=0) if and only if istr is at end of stream or is closed. May block (not return until data are available in the external world).

[inputAll istr] reads and returns the vector v of all bytes remaining in istr up to end of stream. [inputNoBlock istr] returns SOME(v) if some elements v can be read without blocking; returns SOME("") if it can be determined without blocking that istr is at end of stream; returns NONE otherwise. If istr does not support non-blocking input, raises Io.NonblockingNotSupported.

[input1 istr] returns SOME(e) if at least one element e of istr is

available; returns NONE if istr is at end of stream or is closed; blocks if necessary until one of these conditions holds.

[imputN(istr, n)] returns the next n bytes from istr as a vector, if that many are available; returns all remaining bytes if end of stream is reached before n bytes are available; blocks if necessary until one of these conditions holds.

[endOfStream istr] returns false if any elements are available in istr; returns true if istr is at end of stream or closed; blocks if necessary until one of these conditions holds.

the [lookahead istr] returns SOWE(e) where e is the next element in the stream; returns NONE if istr is at end of stream or is closed; blocks if necessary until one of these conditions holds. Does not

BYTE OUTPUT:

[openOut s] creates a new outstream associated with the file named s. If file s does not exist, and the directory exists and is writable, then a new file is created. If file s exists, it is truncated (any existing contents are lost).

1.8 [openAppend s] creates a new outstream associated with the file named s. If file s does not exist, and the directory exists and invitable, then a new file is created. If file s exists, any existing contents are retained, and output goes at the end of the [closeOut ostr] closes stream ostr; further operations on ostr (except for additional close operations) will raise exception Io.Io.

[output(ostr, v)] writes the byte vector v on outstream ostr.

[output1(ostr, e)] writes the byte e on outstream ostr.

device [flushOut ostr] flushes the outstream ostr, so that all data written to ostr becomes available to the underlying file or

The functions below are not yet implemented:

ijξ Raises Io.Io sets istr to the position i. supported on istr. [setPosIn(istr, i)]

[getPosIn istr] returns the current position of istr. Raises Io.Io if not supported on istr.

[endPosIn istr] returns the last position of

ostr. [getDosOut ostr] returns the current position in stream Raises Io.Io if not supported on ostr. [endPosOut ostr] returns the ending position in stream ostr Raises Io.Io if not supported on ostr.

to ostr $[setPosOut(ostr,\ i)] \ sets \ the \ current \ position \ in \ stream \ to i.$

the [mkInstream sistr] creates a state-based instream from functional instream sistr. [getInstream istr] returns the functional instream underlying the state-based instream istr.

[setInstream(istr, sistr)] redirects istr, so that subsequent input is taken from the functional instream sistr.

[mkOutstream sostr] creates a state-based outstream from the

14 BINIO

[getOutstream ostr] returns the outstream underlying the state-based outstream ostr.

[setOutstream(ostr, sostr)] redirects the outstream ostr so that subsequent output goes to sostr.

BINARYMAP

Module Binarymap

Binarymap -- applicative maps as balanced ordered binary trees From SML/NJ lib 0.2, copyright 1993 by AT&T Bell Laboratories Original implementation due to Stephen Adams, Southampton, UK

type ('key, 'a) dict

exception NotFound

```
val mkDict : ('key, 'a) dict * 'key -> order) -> ('key, 'a) dict
val insert : ('key, 'a) dict * 'key * 'a -> ('key, 'a) dict
val find : ('key, 'a) dict * 'key -> 'a option
val remove : ('key, 'a) dict * 'key -> 'a vetion
val remove : ('key, 'a) dict -> int 'key, 'a) dict * 'unit
val listItems : ('key, 'a) dict -> int 'key, 'a) dict -> unit
val app : ('key * 'a -> unit) -> ('key, 'a) dict -> unit
val remap : ('key * 'a -> unit) -> ('key, 'a) dict -> unit
val foldr : ('key * 'a * 'b) -> 'b) -> 'b -> ('key, 'a) dict -> 'b
val fold : ('key * 'a * 'b) -> 'b) -> ('key, 'a) dict -> 'b
val foldr : ('key * 'a * 'b) -> 'b) -> ('key, 'a) dict
val ('key * 'a * 'b) -> ('key, 'a) dict -> 'b
val foldr : ('key * 'a * 'b) -> ('key, 'a) dict -> 'b
val foldr : ('key * 'a * 'b) -> ('key, 'a) dict -> 'b) dict
```

[('key, 'a) dict] is the type of applicative maps from domain type 'key to range type 'a, or equivalently, applicative dictionaries with keys of type 'key and values of type 'a. They are implemented as ordered balanced binary trees.

[mkDict ordr] returns a new, empty map whose keys have ordering

[insert(m, i, v)] extends (or modifies) map m to map i to v.

[find(m, k)] returns v if m maps k to v; otherwise raises NotFound.

[peek(m, k)] returns SOME v if m maps k to v; otherwise returns NONE.

[remove(m, k)] removes k from the domain of m and returns the modified map and the element v corresponding to k. Raises NotFound if k is not in the domain of m.

[numItems m] returns the number of entries in m (that is, the size of the domain of m).

[listItems m] returns a list of the entries $(k,\;\nu)$ of keys k and the corresponding values ν in m, in order of increasing key values.

[app f m] applies function f to the entries (k, v) in m, in increasing order of k (according to the ordering ordr used to create the map or dictionary).

[revapp f m] applies function f to the entries $(k,\;v)$ in m, in decreasing order of k.

[fold] f e m] applies the folding function f to the entries $(k,\ v)$ in m, in increasing order of k.

[foldr f e m] applies the folding function f to the entries $(k,\ v)$ in m, in decreasing order of k.

[map f m] returns a new map whose entries have form (k, f(k,v)), where (k, v) is an entry in m.

[transform f m] returns a new map whose entries have form $(k,\ f\ v)$, where $(k,\ v)$ is an entry in m.

BINARYSET 16

Module Binaryset

Binaryset -- sets implemented by ordered balanced binary trees From SML/NJ lib 0.2, copyright 1993 by AT&T Bell Laboratories Original implementation due to Stephen Adams, Southampton, UK

type 'item set

['item set] is the type of sets of ordered elements of type 'item. The ordering relation on the elements is used in the representation of the set. The result of combining two sets with different underlying ordering relations is undefined. The implementation uses ordered balanced bhinary trees.

[empty ordr] creates a new empty set with the given ordering

[singleton ordr i] creates the singleton set containing i, with the given ordering relation.

[add(s, i)] adds item i to set s.

[addList(s, xs)] adds all items from the list xs to the set s.

[retrieve(s, i)] returns i if it is in s; raises NotFound otherwise.

[peek(s, i)] returns SOME i if i is in s; returns NONE otherwise.

[isEmpty s] returns true if and only if the set is empty.

[equal(s1, s2)] returns true if and only if the two sets have the same elements.

s₂ [isSubset(s1, s2)] returns true if and only if s1 is a subset of

[member(s, i)] returns true if and only if i is in s.

ij. not [delete(s, i)] removes item i from s. Raises NotFound if i is

[numItems s] returns the number of items in set s.

[union(s1, s2)] returns the union of s1 and s2.

[intersection(s1, s2)] returns the intersectionof s1 and s2.

[difference(s1, s2)] returns the difference between s1 and s2 (that is, the set of elements in s1 but not in s2).

BINARYSET

[listItems s] returns a list of the items in set s, in increasing

in increasing [app f s] applies function f to the elements of s, [fold] f e s] applies the folding function f to the entries of the

[revapp f s] applies function f to the elements of s, in decreasing

[foldr f e s] applies the folding function f to the entries of the set in decreasing order.

set in increasing order.

[find $p\ s$] returns SOME i, where i is an item in s which satisfies p, if one exists; otherwise returns NONE.

BOOL 18

Module Bool

```
datatype bool = datatype bool
                              : bool -- bool
                              val not
```

[bool] is the type of Boolean (logical) values: true and false

[scan getc src] scans a boolean b from the stream src, using the stream accessor getc. In case of success, returns $SONE(b, \, rst)$ where b is the scanned boolean value and rst is the remainder of the stream; otherwise returns NONE.

val toString : bool -> string
val fromString : string -> bool option
val scan : (char, 'a) StringCvt.reader -> (bool, 'a) StringCvt.reader [toString b] returns the string "false" or "true" according as b is false or true. [fromString s] scans a boolean b from the string s, after possible initial whitespace (blanks, tabs, newlines). Returns (SOWE b) if s has a prefix which is either "false" or "true"; the value b is the corresponding truth value; otherwise NONE is returned. [not b] is the logical negation of b. Bool -- SML Basis Library

BUFFER

Module Buffer

```
val addChar : buf -> char -> unit
val addString : buf -> string -> unit
val addSubString : buf -> substring -> unit
                                                          val new : int -> buf
val contents : buf -> string
val size : buf -> int
val clear : buf -> unit
val reset : buf -> unit
signature Buffer =
                                          type buf
                                                                                                                                                                                                                                                                end
```

concatenation at the end and automatically expand as necessary. It provides accumulative concatenation of strings in quasi-linear time (instead of quadratic time when strings are concatenated pairwise).

[new hint] creates a new empty buffer. Raises Size if hint <= 0 or hint > String.maxSize.

The argument hint is used as the initial size of the internal string that holds the buffer contents. The internal string is actual automatically reallocated as sontents is stored in the buffer. For best performance, hint should be of the same order of magnitude as the number of characters that are expected to be stored in the buffer. For instance, 80 for a buffer that holds one output line). Nothing bad will happen if the buffer grows beyond that limit, however. In doubt, take hint = 16 for instance.

[contents buf] returns the contents of buf.

[size buf] returns the size of the contents of buf.

[clear buf] emptys buf.

[reset buf] emptys buf and shrink the internal string to the initial hint.

[addChar buf c] appends c at the end of buf.

[addString buf s] appends s at the end of buf.

[addSubString buf ss] appends ss at the end of buf.

BYTE20

Module Byte

```
: Word8Vector.vector * int * int option -> string
: Word8Array.array * int * int option -> string
: Word8Array.array * int * Substring.substring -> unit
                                                : Word8.word -> Char.char

: Char.char -> Word8.word

: Word8Vector.vector -> String.string

: String.string -> Word8Vector.vector
Byte -- SML Basis Library
                                                                                                                                                                                    unpackStringVec
                                                                             val charToByte
val bytesToString
val stringToBytes
                                                                                                                                                                              val unpackStringVe
val unpackString
val packString
                                                   val byteToChar
```

[unpackStringVec (v, i, SOME n)] is the string whose character codes are the bytes of v[i..i+n-1]. Raises Subscript if i<0 or n<0 or i+n>length v. [unpackString (a, i, SOME n)] is the string whose character codes are the bytes of a[i..i+n-1]. Raises Subscript if i<0 or n<0 or i+n>length a. [packString (a, i, ss)] copies the character codes of substring ss into the subarray a[i..i+n-1] where n = Substring.size ss. Raises Subscript if i<0 or i+n > length a. [unpackStringVec $(\nu,\ i,\ NONE)$] is the string whose character codes are the bytes of v[i.length $\nu\text{-}1]$. Raises Subscript if i<0 or i>length ν . [unpackString (a, i, NONE)] is the string whose character codes are the bytes of a[i..length a-1]. Raises Subscript if i<0 or i>length a. [stringToBytes s] is the byte vector of character codes of the string [bytesToString v] is the string whose character codes are the bytes Conversions between bytes and characters, and between byte vectors and strings (character vectors). [byteToChar w] is the character corresponding to the byte w. In Moscow ML, all the above operations take constant time. is, no copying is done. [charToByte c] is the byte corresponding to character c. from vector v.

CALLBACK

Module Callback

accessing C values from ML Callback -- registering ML values with C, and

```
Registering ML values for access from C code:
```

unit : string -> 'a -> u : string -> unit] : string -> bool isRegistered unregister register val val

Accessing C variables and functions from ML:

type cptr

```
ά
                                ^
val getcptr val var val appl val app3 val app4 val app4 val app5 val app5 val app5
```

REGISTERING ML VALUES FOR ACCESS FROM C CODE

80 This example shows how to register the ML function (fn n => 2*n) code that it may be called from C

- The ML side registers the function: Callback.register "myfun" (fn n => 2*n)
- The C side first obtains an ML value pointer: valueptr mvp = get_valueptr("myfun");
- The C side then uses the ML value pointer to obtain an ML value, and uses it: callback(get_value(mvp), Val_long(42)); (2)

Calling get_valueptr may cause the garbage collector to run; hence other live ML values must be registered as GC roots. The garbage collector will never move the ML value pointer; hence it need not be registered as a GC root in the C code. Operation (1) involves a callback to ML, and hence may be slow.

Operation (2) is very fast. If the garbage collector is invoked between the call of get_value() and the use of the ML value, then the value must be registered as a GC root. However, the idiom callback(get value(myp), argl); is safe provided the evaluation of argl does not provoke a garbage

is safe provided the evaluation of argl collection (e.g. if argl is a variable)

The C function get_valueptr returns NULL if nam is not registered.

(and not reregistered) since mvp was obtained; it raises exception Fail if mvp itself is NULL. Every access to the ML value from C code should use the ML valueptr and get_valueptr, otherwise the C code will not know when the value has been unregistered and possibly deallocated. The C function get_value returns NULL if nam has been unregistered

void registervalue(char* nam, value mlval)
void unregistervalue(char* nam)
can be used just as Callback.register and Callback.unregister The C functions (in mosml/src/runtime/callback.c)

The C functions value transp, value arg1) value callbackptr2(valueptr mvp, value arg1, value arg2) value callbackptr2(valueptr mvp, value arg1, value arg2, value arg1, value arg2, value arg3) can be used for callback via an ML value pointer; they will raise

CALLBACK 22

exception Fail if the ML function indicated by mvp has been unregistered

[register nam v] registers the ML value v, so that it can be retrieved from C code under the name nam. If nam has previously been registered and then unregistered, it will be reregistered with the new value. The new value immediately becomes visible to the C side, both via get_valueptr(nam) and via any ML value pointer previously obtained for nam. Raises exception Fall if nam has been registered and not yet unregistered.

[unregister nam] deletes the registration. This prevents C code from Obstaining an ML value pointer for nam and from unaing an ML value pointer already obtained (but does not prevent C from attempting to use a stored ML value previously obtained with the help of the ML value pointer. Mich is unsafe anyway). Does nothing if nam is already unregistered. Raises exception Fail if nam has never been registered.

[isRegistered nam] returns true if nam has been registered and not yet unregistered.

FUNCTIONS FROM ML ACCESSING REGISTERED C VARIABLES AND

This example shows how to register the C function

{ return copy_double(42.42 * Double_val(v)); } value silly_cfun(value v)

(0) The C side registers the function: so that it may be called from ML.

registercptr("mycfun", sillycfun);

(1) The ML side obtains a C pointer and defines an ML function via that pointer:
val sillyztum = appl (getoptr "mycfun") : real -> real
The type ascription is needed to ensure any type safety whatsoever.
Mistakes in the types will lead to crashes, as usual with C.

To the ML side, the new ML function is indistinguishable from val result = sillyfun(3.4) other ML functions (2)

The C function (in mosml/src/runtime/callback.c) void registercptr(char* nam, void* cptr);

is used to register C pointers for access from ML. Only pointers to static C variables, and C functions, should be registered. There is no way to unregister a C pointer.

[cptr] is the type of pointers to C variables and C functions.

[getcptr nam] returns a pointer to the C variable or function registered (by the C side) under the name nam. Raises exception Fail if the name nam has not been registered.

[var cptr] returns the value of the C variable associated with cptr.

app2 cptr arg1 arg2] applies the C function associated with cptr to

[appl cptr arg1] applies the C function associated with cptr to arg1.

[app4 cptr arg1 arg2 arg3 arg4] applies the C function associated with cptr to (arg1, arg2, arg3, arg4). [app3 cptr arg1 arg2 arg3] applies the C function associated with cptr to (arg1, arg2, arg3).

CALLBACK

[app5 cptr arg1 arg2 arg3 arg4 arg5] applies the C function associated with cptr to (arg1, arg2, arg3, arg4, arg5).

CHAR 24

[succ c] returns the character immediately following c, or raises Chr if c = maxChar. [pred c] returns the character immediately preceding c, or raises thr if c = minChar. [isUpper c] returns true if c is a uppercase letter (A to Z). [maxOrd] is the greatest character code; equals ord(maxChar). [isLower c] returns true if c is a lowercase letter (a to z). [chr i] returns the character whose code is i. Raises Chr i<0 or i>maxOrd. [isDigit c] returns true if c is a decimal digit (0 to 9). [maxChar] is the greatest character in the ordering <. [minChar] is the least character in the ordering <. [ord c] returns the code of character c. [char] is the type of characters

CHAR

```
[isPrint c] returns true if c is a printable character (space or visible)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         [isSpace c] returns true if c is a whitespace character (blank, newline,
[isAlpha c] returns true if c is a letter (lowercase or uppercase).
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     [contains s c] returns true if character c occurs in the string s: false otherwise. The function, when applied to s, builds a table and returns a function which uses table lookup to decide whether a given character is in the string or not. Hence it is relatively expensive to compute val p = contains s but very fast to compute
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    isPunct c] returns true if c is a punctuation character, that is,
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  [isChtrl c] returns true if c is a control character, that is, if
                                                                                         [isHexDigit c] returns true if c is a hexadecimal digit (0 to 9 a to f or A to F).
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            [isGraph c] returns true if c is a graphical character, that is, it is printable and not a whitespace character.
                                                                                                                                                                                                                                            [isAlphaNum c] returns true if c is alphanumeric (a letter or a
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          [toLower c] returns the lowercase letter corresponding to c, if c is a letter (a to z or A to Z); otherwise returns c.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             [toUpper c] returns the uppercase letter corresponding to c, if c is a letter (a to z or A to Z); otherwise returns c.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                [isAscii c] returns true if 0 <= ord c <= 127.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    graphical but not alphanumeric.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             tab, vertical tab, new page).

                                                                                                                                                                                                                                                                                                 decimal digit)
```

[notContains s c] returns true if character c does not occur in the string s; false otherwise. Works by construction of a lookup table in the same way as the above function.

p(c) for any given character.

[fromString s] attempts to scan a character or ML escape sequence from the string s. Does not skip leading whitespace. For instance, fromString "\\065" equals #"A".

[toString c] returns a string consisting of the character c, if c is printable, else an ML escape sequence corresponding to c. A printable character is mapped to a one-character string; bell, backspace, tab, newline, vertical tab, form feed, and carriage return are mapped to the two-character strings "\\a", "\\b", "\\\r", "\\\", "\\r", "\\r", "\\r", other characters with code less than 32 are mapped to three-character strings of the form "\\c^2", and characters with codes 127 through 255 are mapped to three-character strings of the form "\\a\c^2", and character strings of the form "\\c^2", and character string chr 10 equals "\\c^2", and character string chr 10 equals "\\c^2", and character string chr 110 equals "\\c^2", and character string chr 120 equals "\c^2", and character string chr 120 equals

26 CHAR

[fromCString s] attempts to scan a character or C escape sequence from the string s. Does not skip leading whitespace. For instance, fromString "\\065" equals #"A".

toString (chr 14) equals "\\016"
toString (chr 127) equals "\\177"
toString (chr 128) equals "\\200"
[<]
[<=]
[<=]
[>>]
[>=]
[>=]
compares character codes. For instance, c1 < c2 returns true
if ord(c1) < ord(c2), and similarly for <=, >, >=.

[compare(c1, c2)] returns LESS, EQUAL, or GREATER, according as c1 is precedes, equals, or follows c2 in the ordering Char.

CHARARRAY

Module CharArray

```
: (int * elem -> bool) -> array -> (int * elem) option

: (int * elem -> unit) -> array -> unit

: (int * elem * 'b -> 'b) -> 'b -> array -> 'b

: (int * elem * 'b -> 'b) -> 'b -> array -> 'b

: (int * elem -> elem) -> array -> 'b

```

[array] is the type of one-dimensional, mutable, zero-based constant-time-access arrays with elements of type Char.char, that is, characters. Arrays al and a2 are equal if both were created by the same call to a primitive, or if both are empty.

All operations are as for Array.array.

```

[slice] is the type of CharArray slices, that is, sub-arrays of CharArray.array values.

The slice (a,i,n) is valid if 0 <= i <= i+n <= size s.

To explicatelly, 0 <= i and 0 <= n and i+n <= size s.

A valid slice sli = (a,i,n) represents the sub-array a[i..i+n-1], so the elements of sli are a[i], a[i+1], ..., a[i+n-1], sthe length of the slice. Only valid slices can be constructed by the functions below.

All operations are as for ArraySlice.slice.

```

[vector] is the type of one-dimensional, immutable, zero-based constant-time-access vectors with elements of type Char.char, that is, characters. Type vector admits equality, and vectors v1 and v2 are equal if they have the same length and their elements are equal. The type vector is the same as String.string.

All operations are as for Vector.vector.

val
val
```

[slice] is the type of CharVector slices, that is, sub-vectors of CharVector.vector values. Since a CharVector.vector is a string, a slice is the same as substring, and slices may be processed using the functions defined as well as those in structure Substring. The slice (a.i,n) is valid if 0 <= i <= i+n <= size s, or equivalently, 0 <= i and 0 <= n and i+n <= size s. A valid slice sli = (a.i,n) represents the sub-vector a[i...i+n-1], so the elements of sli are a[i], a[i+1], ..., a[i+n-1], and n is the length of the slice. Only valid slices can be constructed by these functions.

: (elem * elem -> order) -> slice * slice -> order

val collate

All operations are as for VectorSlice.slice.

COMMANDLINE

Module CommandLine

```
CommandLine -- SML Basis Library
```

val name : unit -> string val arguments : unit -> string list

[arguments ()] returns the command line arguments of the current process. Hence List.nth(arguments (), 0) is the first argument. [name ()] returns the name used to start the current process.

These functions convert times to dates and vice versa, and format

[date] is the type of points in time in a given time zone. If the offset is NONE, then the date is in the local time zone. If the cliset is SOME t, then t is the offset of the main timezone (ignoring daylight savings time) west of UTC . When 0 hours <= t < 12 hours, the represented time is to the when 12 hours <= t < 23 hours, the represented time is to the East of UTC and the local time is $\mathrm{UTC} + (24-t)$.

[date { year, month, day, hour, minute, second, offset }] returns a cannical adte value. Seconds outside the range 0..59 are converted to the equivalent minutes and added to the minutes argument; leap seconds are ignored. Similarly, excess minutes are argument; leap seconds are ignored. Similarly, excess minutes are converted to hours, hours to days, days to months, and months to years. Then the weekday and day number in the year are computed. Leap years are assumed in accordance with the Gregorian calendar, for any year after year 0 A.D.

Example: The current local date in ISO format (e.g. 1998-04-06) can be obtained by using:

fmt "%Y-%m-%d" (fromTimeLocal (Time.now ()))

year including century (e.g. 1997) time zone name if it exists; otherwise the empty string

the percent character

[fromString s] scans a 24-character date from the string s, after possible initial whitespace (blanks, tabs, newlines). The format of the string must be as produced by toString. The fields isDst and offset in the resulting date will be NONE. No check of the

If the offset is greater than one day (24 hours), then the excess days are added to the days, and the offset modulo 24 hours is used.

DATE

```
[yearDay dt] returns the number of the day in the year of dt. January 1 is day 0, and December 31 is day 364 (and 365 in leap years).
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       month number (001..366)
month number (011..12)
minutes (00..59)
locale's equivalent of a.m./p.m.
seconds (00..61, allowing for leap seconds)
week number (00..53), with Sunday as the first day of week of week, with 0 representing Sunday (0..6)
week number (00..53), with Monday as the first day of week 01
locale's appropriate date representation
year of century (00..99)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 [toString dt] returns a 24 character string representing the date dt
                                                                                                                                                                                                                                                                                                                                                                                                                                                                 [isDst dt] returns SOME(true) if daylight savings time is in effect at the date dt; returns SOME(false) if not; and returns NONE if this information is unavailable.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         [fmt fmtstr dt] formats the date dt according to the format string fmtstr. The format string has the same meaning as with the ANSI C function 'strftime'. These ANSI C format codes should work on all
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  [compare(dtl, dt2)] returns LESS, EQUAL, or GREATER, according as date dtl precedes, equals, or follows dt2 in time.
Lexicographically compares the dates. Ignores timezone offset and DST. Does not detect invalid Aares
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            [offset dt] returns NONE if the date dt is in the local time zone; returns SOME t where t is the offset west of UTC otherwise. Thus SOME(Time.zeroTime) is UTC.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 The result may be wrong if the date is not representable as Time.time value. Raises Date if dt is an invalid date.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  a abbreviated weekday name (e.g. "Mon")
A full weekday name (e.g. "Monday")
b abbreviated month name (e.g. "Oct")
c date and time (e.g. "Oct cober")
d and of month (01..31)
H hour (00..23)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          Corresponds to the ANSI C function 'asctime'.
[year dt] returns the year of dt, e.g. 1999
                                                                                                                                                                                                                                                                                                                               [weekDay dt] returns the weekday of dt.
                                                                                                                                                                                                                                                                             [second dt] returns the second of dt.
                                                                                                                                                                                                                     [minute dt] returns the minute of dt.
                                                     [month dt] returns the month of dt.
                                                                                                                                                               [hour dt] returns the hour of dt.
                                                                                                          [day dt] returns the day of dt
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               in the following format
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               platforms:
```

34 DATE

consistency of the date (weekday, date in the month, ...) is performed.

[scan getc src] scans a 24-character date from the stream src, using the stream accessor getc. Otherwise works as fromctring. In case of success, returns SOME(date, rst) where date is the scanned date and rst is the remainder of the stream; otherwise returns NONE.

[fromTimeLocal t] returns the local date at (UTC) time t. The resulting date will have offset = NONE. The fields year, month, day, hour, minute, and second are as expected. The resulting isDst may be NONE if the system cannot determine whether daylight savings time is in effect at the given time. Corresponds to the ANSI C function 'localtime'.

[fromTimeUniv t] is similar to fromTime, but returns the UTC date at (UTC) time t. The resulting date will have offset = SOME Time.zeroTime. Corresponds to the ANSI C function 'gmtime'.

[toTime dt] returns the (UTC) time corresponding to the date dt. Uses the isDst time field if it is present (SOME_) and cannot be calculated from the given date. May raise Date if the given date is invalid. Raises Time. Time if the Date cannot be represented as a Time.time value. At least the dates in the interval 1970-2030 can be represented as Time.time values. Corresponds to the ANSI C function whithme'

[localOffset ()] is the local time zone offset west of UTC. It holds that 0 hours <= localOffset () < 24 hours.

DYNARRAY

Module Dynarray

Dynarray -- polymorphic dynamic arrays a la SML/NJ library

type 'a array

val array : int * '_a -> '_a array
val subArray : 'a array * int * int -> 'a array
val fromList : 'a list * 'a -> 'a array
val sub
: 'a array * int -> 'a) * 'a -> 'a array
val update : int * (int -> 'a) * 'a -> 'a array
val update : 'a array * int * 'a -> unit
val default : 'a array * int * 'a -> unit
val bound : 'a array -> int

['ty array] is the type of one-dimensional, mutable, zero-based unbounded arrays with elements of type 'ty. Type 'ty array does not admit equality.

[array(n, d)] returns a dynamic array, all of whose elements are initialized to the default d. The parameter n is used as a hint of the upper bound on non-default elements. Raises Size if n < 0.

[subArray(a, m, n)] returns a new array with the same default value as a, and whose values in the range [0,n-m] equal the values in a in the range [m,n]. Raises the exception Size if n < m.

[fromList (xs, d)] returns an array whose first elements are those of [xs], and the rest are the default d.

[tabulate(n, f, d)] returns a new array whose first n elements are f 0, f 1, ..., f (n-1), created from left to right, and whose remaining elements are the default d. Raises Size if n < 0.

[sub(a, i)] returns the i'th element of a, counting from 0. Raises Subscript if i < 0.

[update(a, i, x)] destructively replaces the i'th element of a by x. Raises Subscript if i < 0.

[default a] returns the default value of the array a.

[bound a] returns an upper bound on the indices of non-default values

DYNLIB 36

Module Dynlib

```
Dynlib -- dynamic linking with foreign functions
```

```
type symHandle
type dlHandle
```

exception Closed

datatype flag = RTLD_LAZY | RTLD_NOW
val dlopen : { lib : string, flag : flag, global : bool } -> dlHandle
val dlsym : dlHandle -> string -> symHandle
val dlclose : dlHandle -> unit

val var : symHandle -> 'b
val appl : symHandle -> 'al -> 'b
val app2 : symHandle -> 'al -> 'a2 -> 'b
val app3 : symHandle -> 'al -> 'a2 -> 'a3 -> 'b
val app4 : symHandle -> 'al -> 'a2 -> 'a3 -> 'a4 -> 'b
val app5 : symHandle -> 'al -> 'a2 -> 'a3 -> 'a4 -> 'b

Structure Dynlib provides dynamic loading and calling of C functions, using the dlfcn interface. A dynamic library is collection of symbols (C variables and functions).

á Ŷ An ML value passed to or returned from a symbol has type 'value' as defined in src/runtime/mlvalues.h. The C functions should use the macroes defined there to access and produce ML values. When writing a C function, remember that the gabage collector may be activated whenever you allocate an ML value. Also, remember that the garbage collector may move values from the young heap to the be updated. Use that a C pointer pointing into the ML heap may need to be updated. Use the Push_roots and Pop_roots macroes to achieve this.

The [dlHandle] is the type of dynamic library handles. A dynamic library handle is created by opening a dynamic library using dlopen. This will load the library into the runtime system. The dynamic library handle is used for accessing symbols in that library. The library may be closed and removed from the runtime system using dlclose. The same library may be opened more than once, resulting in different library handles. The physical library will be loaded only once, though, and will remain in the runtime system until all handles to the library have been closed.

[symHandle] is the type of symbol handles. A symbol handle is used to access a symbol (variable or function) in the dynamic library, using the functions var, appl, app2, ..., app5. Type safety is the responsibility of the programmer; the runtime system performs no type checking. Hence you are advised to add explicit types whenever you define an ML function in terms of var, app1, ..., app5.

How to create a dynamically loadable library

Assume file "xyz.c" contains your C functions.

To compile xyz.c into xyz.o and then create a dynamic library libxyz.so from xyz.o: gcc -c -o xyz.o xyz.c ld -shared -o libxyz.so xyz.o Under Solaris (ignore the warnings from ld): Under Linux and OSF/1 (Digital Unix):

gcc -c -o xyz.o xyz.c ld -G -B symbolic -z nodefs -o libxyz.so xyz.o Under HP-UX: gcc -fPIC -c -o xyz.o xyz.c ld -b -B symbolic -E -o libxyz.so xyz.o

DYNLIB

If "xyz.o" depends on another library "libabc.a" you may link the required functions into libxyz.so just by adding -labc or libabc.a to the above linker command.

may If "xyz.o" depends on another dynamic library "libabc.so" you may specify this by adding -labc to the above linker command. Then Dynlib.dlopen will automatically load libabc.so before libxyz.so.

in [dlopen { lib, flag, global } will load and open the library in file. Libraries are usually specified just by file name, leaving out the directory path. Linux/Dnix-specific information: Libraries are searched for intose directories mentioned in Libraries are searched for hose directories mentioned in Libraries are searched for hetc/ld.so.cache, in /usr/lib and /lib. (Note that /etc/ld.so.cache is created from /etc/ld.so.comb by running ldconfig; you must be superunser to do that).

If 'global' is true, then the library's global symbols are made available for other libraries subsequently loaded.

[flag] is the type of library loading modes: RTLD_LAZY and RTLD_NOW.

рe [RTLD_LAZY] specifies that only symbol relocations will be performed when calling dlopen, whereas function relocations will b performed later when a function is invoked for the first time (if ever). This is the normal situation.

[RTLD_NOW] specifies that all function relocations must be performed immediately, also for functions that will never be called. This checks that all functions are defined, but may waste

[dlsym dlh nam] returns a symbol handle for the symbol called 'nam in the library associated with dlh. Raises Closed if dlh has been

[dlclose dlh] closes the library handle and deallocates the library if there are no more open handles to this library. The following functions raise Closed if the associated handle has been closed. [var sym] returns the value of the C variable associated with sym. [appl sym arg1] applies the C function associated with sym [app2 sym arg1 arg2] applies the C function associated with sym to (arg1, arg2).

p3 sym arg1 arg2 arg3] applies the C function associated with to (arg1, arg2, arg3). [app3

[app4 sym arg1 arg2 arg3 arg4] applies the C function associated with sym to (arg1, arg2, arg3, arg4).

[app5 sym arg1 arg2 arg3 arg4 arg5] applies the C function associated with sym to (arg1, arg2, arg3, arg4, arg5).

38 FILESYS

Module FileSys

Basis Library

SML

OS.FileSys

```
type dirstream
val openDir : string -> dirstream
val readDir : dirstream -> string option
val rewindDir : dirstream -> unit
val chDir : dirstream -> unit
val chDir : string -> unit
val getDir : unit -> string
val mkDir : string -> unit
val mkDir : string -> unit
val mkDir : string -> unit
val isDir : string -> unit
```

{old: string, new: string} -> unit : string -> Time.time : string * Time.time option -> unit ND | A_WRITE | A_EXEC * access list -> boo datatype access = A_READ | A_WRITE -> string -> string -> bool -> string ^ string string string string string string string : string realPath fullPath isLink readLink modTime setTime rename val access remove val val val val val val

These functions operate on the file system. They raise OS.SysErr in case of errors. [openDir p] opens directory p and returns a directory stream for use by readDir, rewindDir, and closeDir. Subsequent calls to readDir will return the directory entries in some unspecified order.

[readDir dstr] returns SOME(s), consuming an entry s from the directory stream if it is non-empty; returns NONE if it is empty (when all directory entries have been read). Only entries distinct from the parent are and the current arc (that is, .. and .in Unix, DOS, and Windows; see the Path structure) will be returned.

[rewindDir dstr] resets the directory stream as if it had just been opened.

[closeDir dstr] closes the directory stream. All subsequent operations on the stream will raise OS.SysErr.

[chDir p] changes the current working directory to p. This affects calls to the functions use, load, compile in the interactive system, as well as all functions defined in this library. If p specifies a volume name, then this command also changes the current volume (relevant under DOS, Windows, OS/2, etc.).

getDir ()] returns the name of the current working directory.

[mkDir p] creates directory p on the file system.

[rmDir p] removes directory p from the file system.

FILESYS

[isDir p] tests whether p is a directory

[fullPath p] returns a canonical form of path p, where all cocurrences of the arcs ".", "" have been expanded or removed, and (under Unix) symbolic links have been fully expanded. Raises SysErr if a directory on the path, or the file or directory named, does not exist or is not accessible, or if there is a link loop.

[realPath p] behaves as fullPath(p) if p is absolute. If p is relative and on the same volume as the current working directory, it returns a canonical path relative to the current working directory, where superfluous occurrences of the arcs ".", "have been removed, and (under Unix) symbolic links have been fully expanded. Raises SysErr if a directory on the path, or the file or directory named, does not exist or is not accessible, or if there is a link loop. Raises Path if p is relative and on a different volume than the current working directory.

[isLink p] returns true if p names a symbolic link. Raises SysErr if the file does not exist or there is an access violation. On operating systems without symbolic links, it returns false, or raises SysErr if the file does not exist or there is an access violation.

[readLink p] returns the contents of the symbolic link p. Raises SysErr if p does not exist or is not a symbolic link, or there is an access violation. On operating systems without symbolic links, it raises SysErr.

[modTime p] returns the modification time of file p.

[setTime (p, tmopt)] sets the modification and access time of file p. If tmopt is SOME t, then the time t is used; otherwise the current time, that is, Time.now(), is used.

[remove p] deletes file p from the file system.

[rename {old, new}] changes the name of file 'old' to 'new'.

[access] is the type of access permissions:

[A_READ] specifies read access.

[A_WRITE] specifies write access.

[A_EXEC] specifies permission to execute the file (or directory).

[access (p, accs)] tests the access permissions of file p, expanding symbolic links as necessary. If the list accs of required access permission is empty, it tests whether p exists. If accs contains A.FRAD, A.WITE, or A.EXEC, respectively, it tests whether the user process has read, write, or execute permission for the file

the file.

Under Unix, the access test is done with the 'real' user id and group id and group id (as opposed to the 'effective' user id and group id) of the user process. Hence access("file", [A_READ]) may return false, yet the file may be readable by the process, in case the effective user id or group id has been changed by setuid.

[fileSize p] return the size, in bytes, of the file p. Raises SysErr if p does not exist or its directory is not accessible.

[tmpName ()] returns a file name suitable for creating a fresh temporary file. Note that there is no guarantee that the file name will be unique, since a file of that name may be created between the call to tmpName and a subsequent call to openOut which creates the file. The file name will be absolute, usually of the form /tmp/xxxxxxxxx provided by POSIX tmpnam (3).

[file id] is the type of unique identities of file system objects (including device ids and volume ids, but possibly insensitive to

40 FILE

volume changes on removable volumes, such as tapes and diskettes). The set of file ids is equipped with a total linear order.

[fileId p] returns the file_id of the file system object named by path p. It holds that fileId pl = fileId p2 if and only if pl and p2 name the same file system object.

[hash fid] returns a hashvalue for fid, suitable for use in hashtable of file ids (and hence files).

If fidl = fid2 then hash fidl = hash fid2.

[compare (fidl, fid2)] returns LESS, EQUAL, or GREATER, according as fidl precedes, equals, or follows fid2 in the total linear order on file ids. This is suitable for e.g. an ordered binary tree of file ids (and hence files).

FILESYS

Module Gdbm

Gdbm -- GNU gdbm persistent string hashtables -- requires Dynlib

type table

```
read/write, create if necessary
         read-only access (nonexclusive)

```

[table] is the type of an opened table. A value of type table can be used only in the argument f to the withtable function. This makes sure that the table is closed after use.

[Openmode] is the type of opening modes. Read-only access (READER) is non-exclusive; read/write access (WRITER, WRCREAT, NEWDB) is exclusive.

[withtable (nam, mod) f] first opens the table db in file nam with mode mod, then applies f to db, then close db. Makes sure to close db even if an exception is raised during the evaluation of f(db). Raises GdbmError with an informative message in case the table cannot be opened. B.g. the table cannot be opened for reading if already opened for writing, and cannot be opened for writing, and cannot be opened for writing if already opened for reading.

A table is only guaranteed to work properly if created by withtable using open modes WRCREAT or NRUNB. If you create a table by creating and then opening an empty file, then numItems, listKeys, listItems, etc. will raise an exception.

[withtables nammod f], where nammod = [(naml, modl), ..., (namn, modn)],
is equivalent to
 withtable (naml, modl) (fn dbl =>
 withtable (naml, modl) (fn dbl =>

That is, first opens the databases dbl, db2, ... in that order in files naml, nam2, ... with modes mod1, mod2, ..., then applies f to [db1, db2, ...], and finally closes [db1, db2, ...]. Makes sure to close all databases even if an exception is raised during the opening of db1, db2, ... or during the evaluation of f[db1, db2, ...].

42 GDBM

[add db (k,v)] adds the pair (k,v) to db. Raises AlreadyThere if there is a pair (k, \bot) in db already. Raises NotWriter if db is not opened in write mode.

[insert db $(k,\ v)$] adds the pair $(k,\ v)$ to db, replacing any pair $(k,\)$ at k if present. Raises NotWriter if db is not opened in write mode.

[find db k] returns v if the pair $(k,\ v)$ is in db; otherwise raises NotFound.

[peek db k] returns SOME v if the pair (k, v) is in db; otherwise returns NONE.

[haskey db k] returns true if there is a pair $(k, _)$ in db; otherwise returns false.

[remove db k] deletes the pair (k, _) from the table if present; otherwise raises NotFound. Raises NotWriter if db is not opened write mode.

[listKeys db] returns a list of all keys in db in an unspecified

[numItems db] is the number of (key, value) pairs in db Equivalent to length(listKeys db).

[listItems db] returns a list of all (key, value) pairs in db in some order. Equivalent to List.map (fn key => (key, find(db,key))) (listKeys db)

[app f db] is equivalent to List.app f (listItems db), provided the function f does not change the set of keys in the table. Otherwise the effect is unpredictable.

Otherwise the effect is unpredictable.

[map f db] is equivalent to List.map f (listItems db), provided the function f does not change the set of keys in the table.

Otherwise the result and effect are unpredictable.

[fold f a db] is equivalent to List.foldr ($(k, v), r) \Rightarrow f(k, v, r)$) a (listItems db) provided the function f does not change the set of keys in the table. Otherwise the result and effect are unpredictable.

[fastwrite] can be set to speed up writes to a table. By default, ifsarwrite is false and every write to a table will be followed by file system synchronization. This is safe, but slow if you perform thousands of writes. However, if !fastwrite is true when calling withtable, then writes may not be followed by synchronization, which may speed up writes considerably. In any case, the file system is synchronized before withtable returns.

[reorganize db] has no visible effect, but may be called after a lot of deletions to shrink the size of the table file.

GDIMAGE 4

This is an interface to version 1.7.3 of Thomas Boutell's gd image package for creating PNG images.

[image] is the type of images being drawn. They can be created from scratch, imported from PNG files, and exported to PNG files.

All functions correctly clip to the actual size of the image.

[color] is the type of colors. Currently there can be at most 256 different colors in an image.

[style] is the type of drawing styles. A style is either a color or transparent.

[mode] is the type of drawing modes for line drawing and filling. It may be one of

Color c

where c is a color

Transparent Brushed img Styled stys

for line drawing using the given image as brush in the drawing, cyclically using the styles (vis, img) (vis, img) for line drawing, using the given image as a brush, cyclically switching it on and off according to the given bool vector StyledBrushed

for filling, using the given image as a tile Tiled img

font] is the type of fonts: Tiny, Small, MediumBold, Large, Giant

[rgb] is the type of (r, g, b) triples, where the components indicate color intensity as an integer value in the range 0..255.

t [xy] is the type of pairs, used for (x, y) coordinates and to indicate dimensions (width, height). The origin (0, 0) is the upper left-hand corner of the image. The x coordinates increase the right; the y coordinates increase downwards.

h) and be [image $(w,\ h)$ rgb] creates a new empty image with size $(w,\ the\ background\ color\ rgb.\ Raises\ Fail\ if\ the\ image\ cannot$

Raises [fromPng filename] reads an image from the given PNG file. Rais: Fail if the file does not exist or does not contain a PNG image. (size img] returns (w, h) where w is the width and h the height of $\lim_{n \to \infty} \frac{1}{n}$

toPng img filename] write the image to the given file in PNG

[stdoutPng img] writes the image to standard output in PNG format, preceded by the HTTP header "Content-type: image/png/n\n". Useful in CGI scripts.

[color img rgb] returns the color code corresponding to rgb in the color table of img. Reuses the color code if it has already been allocated; otherwise allocates the color if possible; otherwise returns an approximation to the color rgb.

[htmlcolors im] returns a record containing the 16 standard HTML colors: aqua, black, blue, fuchsia, gray, green, lime, marcon, navy, blue, purple, rad, sliver, teal, white, yellow. This call will allocate all these colors in the color table of the image, even if you do not use all of them.

r, g, b are the component [rgb img color] returns (r, g, b) where r, g, b are the cintensities of the given color in the color table of img.

[getTransparent img] returns SOME c where c is the 'transparent' color of the image, if any; otherwise returns NONE.

[setTransparent img col] makes the given color transparent in the

GDIMAGE

[noTransparent img] makes all colors non-transparent in the image. This is useful for images that are to be used as tiles for filling. Such images are not allowed to have a transparent color.

[drawPixel img mode xy] draws the pixel in img at xy using given mode

xy2[drawLine img mode (xy1, xy2)] draws a line in img from xy1 to using the given mode.

[drawRect img mode $(xy1,\ xy2)$] draws a rectangle in img with opposing corners xy1 and xy2 using the given mode.

[fillRect img mode $(xy1,\ xy2)$] draws a filled rectangle in img with opposing corners xy1 and xy2 using the given mode.

[drawPolygon img mode xys] draws a polygon in img with corners as given by the vector xys of coordinates using the given mode.

[fillPolygon img mode xys] draws a filled polygon in img with corners as given by the vector xys of coordinates using the given

[drawhrc img mode $\{$ c, wh, from, to $\}$] draw part of an ellipsis arc in img, with center c, width and height wh, using the given 'from' and 'to' angles, given in degrees (0..360).

[fill img mode xy] fills the region in img around xy which has the same color as the point at img, using the given mode.

[fillBorder img mode xy col] fills the region in img around xy which is delimited by the color col, using the given mode.

[copy { src, srcxy, srcwh, dst, dstxy }] copies part of the image src into the image dst, without rescaling. More precisely, copies the subimage of src whose upper left-hand corner is srcxy and whose size is srcwh, into the subimage of dst whose upper left-hand corner is dstxy. The images src and dst may be the same, but if the subimages overlap, then the result is unpredictable.

[copyResize { src, srcxy, srcwh, dst, dstxy, dstwh }] copies part of the image src into the image dst, rescaling to the given size dstwh of the destination subimage. Otherwise works as copy.

[char img col font xy ch] draws the character ch left-right (to be read from south) in img at xy using the given color.

[charUp img col font xy ch] draws the character ch bottom-up (to be read from east) in img at xy using the given color.

þe [string img col font xy s] draws the string s left-right (to read from south) in img at xy using the given color. þ [stringUp img col font xy s] draws the string s bottom-up (to read from east) in img at xy using the given color.

[charsize font] returns (w, h) where w is the width and h the height, in pixels, of each character in the given font.

GENERAL 84

['a frag] is the type of quotation fragments, resulting from the parsing of quotations ' ... ' and antiquotations. See the Moscow ML Owner's Manual.

[Bind] is the exception raised when the right-hand side value in a valbind does not match the left-hand side pattern.

Chr] signals an attempt to produce an unrepresentable character

[Div] signals an attempt to divide by zero.

[Domain] signals an attempt to apply a function outside its domain of definition; such as computing Math.sgrt($^{-1}$).

[Fail] signals the failure of some function, usually in the Moscow ML specific library structures.

[Match] signals the failure to match a value against the patterns in a case, handle, or function application.

[Option] is raised by Option.valOf when applied to NONE.

Overflow] signals the attempt to compute an unrepresentable number

array, dynarray, list, string, substring, vector or weak array. Subscript] signals the attempt to use an illegal index in an

[Size] signals the attempt to create an array, string or vector that is too large for the implementation.

[Graphic] signals the failure of Graphics primitives (DOS only)

[Interrupt] signals user interrupt of the computation.

[Invalid_argument] signals the failure of a function in the runtime

[Io { function, name, cause }] signals the failure of an input/output operation (function) when operating on a file (name). The third field (cause) may give a reason for the failure.

[Out_of_memory] signals an attempt to create a data structure too large for the implementation, or the failure to extend the heap or

[SysErr (msg, err)] signals a system error, described by msg. A system error code may be given by err. If so, it will usually hold system error code may be gi that msg = OS.errorMsg err.

Basis Library values

[! rf] returns the value pointed to by reference rf.

 $[:=(rf,\,e)]$ evaluates rf and e, then makes the reference rf point to the value of e. Since := has infix status, this is usually written

[o(f, g)] computes the functional composition of f and g, that is, fn x => f(g x). Since o has infix status, this is usually written f o g

[ignore e] evaluates e, discards its value, and returns (): unit.

[before(el, e2)] evaluates el, then evaluates e2, then returns the value of e1. Since before has infix status, this is usually written el before e2

[exnName exn] returns a name for the exception constructor in exn. Never raises an exception itself. The name returned may be that of any exception constructor aliasing with exn. For instance, let exception B1; exception E2 = E1 in exnName E2 end

GENERAL

```
may evaluate to "E1" or "E2"
```

[exnMessage exn] formats and returns a message corresponding to exception exn. For the exceptions defined in the SML Basis Library, the message will include the argument carried by the exception.

Additional Moscow ML top-level values

Ġ. [not b] returns the logical negation of

[4] is the string concatenation operator.

[=] is the polymorphic equality predicate.

[<>] is the polymorphic inequality predicate.

[ceil r] is the smallest integer >= r (rounds towards plus infinity). May raise Overflow.

[floor r] is the largest integer <= r (rounds towards minus infinity). May raise Overflow.

[real i] is the floating-point number representing integer Equivalent to Real.fromInt.

[round r] is the integer nearest to r, using the default rounding mode. May raise Overflow.

zero [trunc r] is the numerically largest integer between r and (rounds towards zero). May raise Overflow.

[vector [x1, ..., xn]] returns the vector #[x1, ..., xn].

[< (x1, x2)] [<=(x1, x2)] [> (x1, x2)] [>=(x1, x2)]

These are the standard comparison operators for arguments of type int, Word.word, Word8.word, real, char or string.

[makestring v] returns a representation of value v as a string, for v of type int, Word.word, WordB.word, real, char or string.

Мау $[\,\sim\,x]$ is the numeric negation of x (which can be real or int). raise Overflow. [abs x] is the absolute value of x (which can be real or int). May raise Overflow.

[+ (e1, e2)] [- (e1, e2)] [* (e1, e2)]

These are the standard arithmetic operations for arguments of type int, Word word, Word8.word, and real. They are unsigned in the case of Word.word and Word8.word. May raise Overflow.

[/ (el, e2)] is the floating-point result of dividing el by e2.
May raise Div and Overflow.

[div(el, e2)] is the integral quotient of dividing el by e2 for arguments of type int, Word.word, and Word8.word. See Int.div and Word.div for more details. May raise Div, Overflow.

for Int.mod and [mod(el, e2)] is the remainder when dividing el by e2, arguments of type int, Word, word, and Word8.word. See Word.mod for more details. May raise Div.

```

['item set] is the type of sets of elements of type 'item, with a given hash function and equality predicate.

[empty (hash, equal)] creates a new empty set with the given hash function and equality predicate. It must hold that equal(x, y) implies hash x = hash y.

[singleton (hash, equal) i] creates the singleton set containing i, with the given hash function and equality predicate.

[singleton (hash, equal) i] creates the singleton set containing i, with the given hash function and equality predicate.

[member(s, i)] returns true if and only if i is in s.

[retrieve(s, i)] returns SOME i if i is in s; returns NONE otherwise.

[addist(s, xs)] adds item i to set s.

[addist(s, xs)] adds all items from the list xs to the set s.

[delete(s, i)] removes item i from s. Raises NotFound if i is not in s.

[isEmpty s] returns true if the set is empty; false otherwise.

[equal(s1, s2)] returns true if and only if the two sets have the same elements.

[isSubset(s1, s2)] returns true if and only if s1 is a subset of s2.

[numltems s] returns the number of items in set s.

[listItems s] returns a list of the items in set s, in some order.

HASHSET

[app f s] applies function f to the elements of s, in some order.

[fold f $\,$ e $\,$ s] applies the folding function f to the entries of the set in some order.

[find p s] returns SOME i, where i is an item in s which satisfies p, if one exists; otherwise returns NONE.

[hash s] returns the hashcode of the set, which is the sum of the hashcodes of its elements, as computed by the hash function given when the set was created.

[polyHash v] returns a system-defined hashcode for the value v. This pseudo-polymorphic hash function can be used together with the standard equality function (=) to create a Hashset for any type that admits equality, as follows:

val set = Hashset.empty (Hashset.hash, op =);

HELP52

Module Help

```
help functions
Help -- on-line
```

```
: int ref
: string list ref
: string list ref
: {term : string, file : string, title : string} list ref
: string vector ref
: (string -> unit) ref
: string -> unit)
: string -> unit
                              val displayLines :
val helpdirs :
val indexfiles :
val specialfiles :
val welcome :
val browser :
val defaultBrowser :
val help
```

[help s] provides on-line help on the topic indicated by string s.

gives an overview of the Moscow ML library. provides help on identifier id (case-insensitive). help "lib"; help "id"; If exactly one identifier in the library matches id (case-insensitive), then the browser opens the signature defining that identifier, positioning the first occurrence of id at the center of the screen.

If more than one identifier matches id (case-insensitive), then a small menu lists the signatures containing the identifier. To invoke the browser, just type in the number of the desired signature.

The browser accepts the following commands, which must be followed by a newline:

```
move down by half a screen move up by half a screen move to top of file move to bottom of file cyclically search for string str in help file (case-insensitive) search for next occurrence of str
                                                                         /str
   brrd
```

A newline by itself moves down one screen (24 lines).

quit the browser

[helpdirs] is a reference to a list of additional directories to be searched for help files. The directories are searched in order, after the -stdlib directory.

[indexfiles] is a reference to a list of full paths of help term index files. Setting 'indexfiles' affects subsequent invocations of 'help'. (Every invocation of 'help' reads the index files anew).

[specialfiles] is a reference to a list of {term, file, title} records, each of which maps a search term to the specified file with the specified title (in the browser). The string in the 'term' field should be all lowercase, since the argument passed to 'help' will be converted to lowercase.

welcome] is a reference to the text shown in response to the query nelp "". This is a vector of lines of text. help "".

on the [browser] is a reference to the function that gets invoked text of the help file. Initially set to defaultBrowser.

[defaultBrowser] is the default (built-in) help browser.

[displayLines] is a reference to the size of the display (window) assumed by the defaultBrowser; initially 24 lines. Set it to the actual size of your window for best results.

Module Int

INT

Int -- SML Basis Library

type int = int

	w.c		<pre>StringCvt.radix -> (char, 'a) StringCvt.reader -> (int, 'a) StringCvt.reader StringCvt.radix -> int -> string int -> string string -> int option Overflow</pre>

rromstring : string

the number of significant bits in an 32-bit architectures and 63 in 64-bit where n is n is 31 in [precision] is SOME n, integer. In Moscow ML architectures.

[minInt] is SOME n, where n is the most negative integer.

[maxInt] is SOME n, where n is the most positive integer.

[-] are the usual operations on integers. They raise Overflow if the result is not representable as an integer.

[abs] returns the absolute value of its argument. Raises Overflow if applied to the most negative integer.

[div] is integer division, rounding towards minus infinity. Evaluating i div 0 raises Div. Evaluating i div ~1 raises Overflow if i is the most negative integer.

then [mod] is the remainder for div. If g=i div d and r=i mod d tit holds that gd+r=i, where either 0 <= r < d or d < r <= 0. Evaluating i mod 0 raises Div, whereas i mod $\sim 1=0$, for all i.

[quot] is integer division, rounding towards zero. Evaluating quot(i, 0) raises Div. Evaluating quot(i, \sim 1) raises Overflow if is the most negative integer.

INT 54

[rem(i, d)] is the remainder for quot. That is, if $q=\operatorname{quot}(i,\,d)$ and $r=\operatorname{rem}(i,\,d)$ then d*q+r=i, where r is zero or has the same sign as i. If made infix, the recommended fixity for quot and rem is

infix 7 quot rem

 $[\min(x, y)]$ is the smaller of x and

 $[\max(x, y)]$ is the larger of x and y.

[sign x] is ~1, 0, or 1, according as x is negative, zero, or positive.

. |-

[>] [>] are the usual comparisons on integers.

[compare(x, y)] returns LESS, EQUAL, or GREATER, according as x is less than, equal to, or greater than y.

[sameSign(x, y)] is true iff sign x = sign y.

[toInt x] is x (because this is the default int type in Moscow ML).

[fromInt x] is x (because this is the default int type in Moscow ML).

int type in Moscow ML). [toLarge x] is x (because this is the largest

[fromLarge x] is x (because this is the largest int type in Moscow ML).

[fmt radix i] returns a string representing i, in the radix (base) specified by radix.

output format];~	~?[0-7]+	-5[0-0]+	~?[0-9A-F]+
	. 2	8	10)	16)
	(base	(base	(base	(base
tion	binary	octal	decimal	hexadecimal
description	signed	signed	signed	signed
radix	ιщ	OCT	DEC	HEX

[toString i] returns a string representing i in signed decimal format. Equivalent to (fmt DEC i).

[fromString s] returns SOME(i) if a decimal integer numeral can be scanned from a prefix of string s, ignoring any initial whitespace; returns NNE otherwise. A decimal integer numeral must have form, after possible initial whitespace: [+~-]?[0-9]+

[scan radix getc charsrc] attempts to scan an integer numeral from the character source charsrc, using the accessor getc, and ignoring any initial whitespace. The radix argument specifies the base of the numeral (BIN, OCT, DEC, HEX). If successful, it returns SOWE(i, rest) where i is the value of the number scanned, and rest is the unused part of the character source. A numeral must have form, after possible initial whitespace:

[+~-]?[0-1]+ [+~-]?[0-7]+ [+~-]?[0-9]+ [+~-]?[0-9a-fA-F]+ BIN

val foldr
val foldr
val manfoldr
val manfoldr
val manfoldr

['a intmap] is the type of applicative maps from int to

[empty] creates a new empty map

[insert(m, i, v)] extends (or modifies) map m to map i to

[retrieve(m, i)] returns v if m maps i to v; otherwise raises

[peek(m, i)] returns SOME v if m maps i to v; otherwise NONE.

Raises NotFound [remove(m, i)] removes i from the domain of m and returns the lified map and the element v corresponding to i. is not in the domain of m. modified map and

size [numItems m] returns the number of entries in m (that is, the the domain of m). integers i and of i. οĘ [listItems $\mathfrak m$] returns a list of the entries (i, $\mathfrak v$) of the corresponding values $\mathfrak v$ in $\mathfrak m$, in increasing order

in [app f m] applies function f to the entries (i, v) in m, JО increasing order

ij Ĕ, [revapp f m] applies function f to the entries (i, v) in decreasing order of i.

> [fold] f e m] applies the folding function f to the entries (i, in m, in increasing order of i.

5 [foldr f e m] applies the folding function f to the entries (i, in m, in decreasing order of i.

[map f m] returns a new map whose entries have form (i, f(i,v)), where (i, v) is an entry in m.

[transform f m] returns a new map whose entries have form (i, f(i,v)), where (i, v) is an entry in m.

INTSET 99

Module Intset

Intset -- applicative sets of integers From SML/NJ lib 0.2, copyright 1993 by AT&T Bell Laboratories Original implementation due to Stephen Adams, Southampton, UK

type intset

exception NotFound

```
val empty
val singleton int -> intset
val addi.
val addi.
val addi.
val addi.
val isEmpty intset * int list -> intset
val isEmpty intset -> bool
val isEmpty intset -> bool
val isEmpty intset -> bool
val isSubate intset * intset -> bool
val member intset * int -> bool
val member intset * int -> bool
val delete
val union intset * int -> intset
val union intset * intset -> intset

val foldr (int * bool) -> intset -> 'b
val foldr (int * bool) -> intset -> 'b
val foldr (int * bool) -> intset -> 'b
```

[intset] is the type of sets of integers.
[empty] is the empty set of integers.
[singleton i] is the singleton set containing i.
[add(s, i)] adds item i to set s.
[addList(s, xs)] adds all items from the list xs to the set s.
[isEmpty s] returns true if and only if the set is empty.
[equal(s1, s2)] returns true if and only if the two sets have the same elements.

[isSubset(s1, s2)] returns true if and only if s1 is a subset of s2

[member(s, i)] returns true if and only if i is in s.

[delete(s, i)] removes item i from s. Raises NotFound if i is not in s.

[numItems s] returns the number of items in set s.

[union(s1, s2)] returns the union of s1 and s2.

[intersection(s1, s2)] returns the intersection of s1 and s2.

[difference(s1, s2)] returns the difference between s1 and s2 (that is, the set of elements in s1 but not in s2).

[listItems s] returns a list of the items in set s, in increasing

(app f s] applies function f to the elements of s, in increasing

[revapp f s] applies function f to the elements of s, in decreasing order.

[fold] f e s] applies the folding function f to the entries of the set in increasing order.

INTSET

[foldr f e s] applies the folding function f to the entries of the set in decreasing order.

[find $p\ s$] returns SOWE i, where i is an item in s which satisfies p, if one exists; otherwise returns NONE.

58 LEXING

Module Lexing

Lexing -- run-time library for lexers generated by mosmllex Closely based on the library for camllex. Copyright 1993 INRIA, France

local open Obj in

type lexbuf

val createLexerString : string -> lexbuf
val createLexer : (CharArray.array -

val createLexer : (CharArray.array -> int -> int) -> lexbuf
val getLexeme
 : lexbuf -> string
val getLexemeChar : lexbuf -> int -> char
val getLexemeStart : lexbuf -> int
val getLexemeEnd : lexbuf -> int

For internal use in generated lexers:

val dummyAction : lexbuf -> obj
val backtrack : lexbuf -> 'a
prim_val getNextChar : lexbuf -> char = 1 "get_next_char"

These functions are for use in mosmllex-generated lexers. For further information, see the Moscow ML Owner's Manual. For examples, see mosml/examples/lexyacc and mosml/examples/calc.

[lexbuf] is the type of lexer buffers. A lexer buffer is the argument passed to the scanning functions defined by the mosmllex-generated scanners. The lexer buffer holds the current state of the scanner, plus a function to refill the buffer from the stand

[createLexerString s] returns a lexer buffer which reads from the given string s. Reading starts from the first character in the string. An end-of-input condition is generated when the end of the string is reached.

[createLexer f] returns a lexer buffer that will use the given function f for reading additional input. When the lexer needs more characters, it will call the given function as (f carr n), where carr is a character array, and n is an integer. The function subould put at most characters or in carr, starting at character number 0, and return the number of characters actually stored. A return value of 0 means end of input.

A lexer definition (input to mosmllex) consists of fragments of this form

where the lhs are regular expressions matching some string of

LEXINC

characters, and the rhs are corresponding semantic actions, written in ${\rm ML}$. The following functions can be used in the semantic actions:

[getLexeme lexbuf] returns the string matched by the left-hand side regular expression.

[getLexemeChar lexbuf i] returns character number i in the matched string.

[getLexemeStart lexbuf] returns the start position of the matched string (in the input stream). The first character in the stream has position $\mathbf{0}$.

[getLexemeEnd lexbuf] returns the end position, plus one, of the matched string (in the input stream). The first character in the stream has position $\mathbf{0}$.

LIST 9

Module List

val
```

['a list] is the type of lists of elements of type

[null xs] is true iff xs is nil.

Raises Empty if xs is nil [hd xs] returns the first element of xs.

[tl xs] returns all but the first element of xs. Raises Empty if xs is nil.

nil. Raises Empty if xs is [last xs] returns the last element of xs.

0 [nth(xs, i)] returns the i'th element of xs, counting from Raises Subscript if i<0 or i>=length xs. [take(xs, i)] returns the first i elements of xs. Raises Subscript if i<0 or i>length xs.

XS <= length [drop(xs, i)] returns what is left after dropping the first i elements of xs. Raises Subscript if i<0 or i>length xs. It holds that take(xs, i) @ drop(xs, i) = xs when 0 <= i <= le

[length xs] returns the number of elements in xs.

[rev xs] returns the list of xs's elements, reversed.

[xs @ ys] returns the list which is the concatenation of xs and ys.

LIST

```
[concat xss] returns the list which is the concatenation of all the
```

ys)] is equivalent to rev xs @ ys, but more efficient [revAppend(xs,

[app f xs] applies f to the elements of xs, from left to right

[map f xs] applies f to each element x of xs, from left right, and returns the list of f's results.

[mapPartial f xs] applies f to each element x of xs, from left to right, and returns the list of those y's for which f(x) evaluated to SOME y.

[find p xs] applies p to each element x of xs, from left to right, until p(x) evaluates to true; returns SOME x if such an x exists, otherwise NONE.

[filter p xs] applies p to each element x of xs, from left to right, and returns the sublist of those x for which p(x) evaluated to true. [partition p xs] applies p to each element x of xs, from left to right, and returns a pair (pos, neg) where pos is the sublist of those x for which p(x) evaluated to true, and neg is the sublist of those for which p(x) evaluated to false.

[foldr op\$ e xs] evaluates x1 % (x2 % (... % (x(n-1) % (xn % e)) where xs = [x1, x2, ..., x(n-1), xn], and % is taken to be infixed

[foldl op% e xs] evaluates xn $\{(x(n-1) \ \ \ \ \dots \ \ \ (x2 \ \ \ (x1 \ \ \ \ \)))\}$ where xs = [x1, x2, ..., x(n-1), xn], and $\{$ is taken to be infixed.

× ç [exists p xs] applies p to each element x of xs, from left t right until p(x) evaluates to true; returns true if such an exists, otherwise false.

an x [all p xs] applies p to each element x of xs, from left to right until p(x) evaluates to false; returns false if such exists, otherwise true. [collate cmp [xs, ys]] returns LESS, EQUAL or GREATER according as xs precedes, equals or follows ys in the lexicographic ordering on lists induced by the ordering cmp on elements.

[tabulate(n, f)] returns a list of length n whose elements are f(0), f(1), ..., f(n-1), created from left to right. Raises Size if n<0.

[getItem xs] attempts to extract an element from the list xs. It returns NONE if xs is empty, and returns SOME (x, xr) if xs=x::xr. This can be used for scanning booleans, integers, reals, and so on from a list of characters. For instance, to scan a decimal integer from a list cs of characters, compute Int.scan StringCvt.DEC List.getItem cs

These functions process pairs (xs, ys) of lists. There are three groups of functions:

- zip, map, app, all, exists, foldr and foldl raise no exception when the argument lists are found to be of unequal length; the excess elements from the longer list are simply disregarded.
- foldlEq raise exception lists are found to be of zipEq, mapEq, appEq, foldrEq and UnequalLengths when the argument unequal length.
- allEq raises no exception but returns false if the lists are found to have unequal lengths (after traversing the lists).

 $\{\text{zip }(xs,\ ys)\}$ returns the list of pairs of corresponding elements from xs and ys.

[unzip xys] returns a pair (xs, ys), where xs is the list of first components of xys, and ys is the list of second components from xys. Hence zip (unzip xys) has the same result and effect as xys.

[map f (xs, ys)] applies function f to the pairs of corresponding elements of xs and ys from left to right and returns the list of results. Hence map f (xs, ys) has the same result and effect as List.map f (zip (xs, ys)).

corresponding [app f (xs, ys)] applies function f to the pairs of correclements of xs and ys from left to right and returns (). app f (xs, ys) has the same result and effect as List.app f (zip (xs, ys)). [all p (xs, ys)] applies predicate p to the pairs of corresponding elements of xs and ys from left to right until p evaluates to false or ne or both lists is exhausted; returns true if p is true of all such pairs; otherwise false. Hence all p (xs, ys) has the same result and effect as List.all p (zip (xs, ys)).

[exists p (xs, ys)] applies predicate p to the pairs of corresponding elements of xs and ys from left to right until p evaluates to true or one or both lists is exhausted; returns true if p is true of any such pair; otherwise false.

If p is true of xs, ys) has the same result and effect as List.exists p (xs, ys). Also, exists p (xs, ys). Also, exists p (xs, ys).

[foldr f e (xs, ys)] evaluates f(x1, y1, f(x2, y2, f(..., f(xn, yn, e)))) where xs = [x1, x2, ..., x(n-1), xn, ...], ys = [y1, y2, ..., y(n-1), yn, ...],

LISTPAIR

```
e)))
and n = min(length xs, length ys). Equivalent to List.foldr (fn ((x, y), r) => f(x, y, r)) e (zip(xs, ys)).

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         [zipEq (xs, ys)] returns the list of pairs of corresponding elements from xs and ys. Raises UnequalLengths if xs and ys do have the same length.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             [allEq p (xs, ys)] works as all p (xs, ys) but returns false if and ys do not have the same length. Equivalent to all p (xs, ys) andalso length xs = length ys.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       [mapEq f (xs, ys)] applies function f to pairs of corresponding elements of xs and ys from left to right, and then returns the lof results if xs and ys have the same length, otherwise raises UnequalLengths. If f has no side effects and terminates, then it is equivalent to List.map f (zipEq (xs, ys)).
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             corresponding
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  [appEq f (xs, ys)] applies function f to pairs of correspondenests of xs and ys from left to right, and then raises UnequalLengths if xs and ys have the same length.

Module Listsort

Listsort

```
sort : ('a * 'a -> order) -> 'a list -> 'a list
sorted : ('a * 'a -> order) -> 'a list -> bool
merge : ('a * 'a -> order) -> 'a list -> 'a list
mergeUniq : ('a * 'a -> order) -> 'a list * 'a list -> 'a list
eqclasses : ('a * 'a -> order) -> 'a list -> 'a list list
                                  val sorted : val merge : val mergeUniq : val eqclasses :
   val sort
```

[sort ordr xs] sorts the list xs in nondecreasing order, using the given ordering. Uses Richard O'Keefe's smooth applicative merge sort.

[sorted ordr xs] checks that the list xs is sorted in nondecreasing order, in the given ordering.

the [merge ordr (xs, ys)] returns a sorted list of the elements of sorted lists xs and ys, preserving duplicates. Both xs and ys be sorted by ordr, that is, must satisfy sorted ordr xs andalso sorted ordr xs andalso sorted ordr xs.

sorted ordr (merge ordr (xs, ys))

[mergeUniq ordr (xs, ys)] returns a sorted list of the elements of the sorted lists xs and ys, without duplicates. Both xs and ys must be sorted by ordr.

[eqclasses ordr xs] returns a list [xs1, xs2, ..., xsn] of non-empty equivalence classes of xs, obtained by sorting the list and then grouping consecutive runs of elements that are EQUAL by ordr. If ordr is a total order, then it holds for xi in xsi and xj in xsj: ordr(xi, xj) = EQUAL iff i=j and ordr(xi, xj) = GEASTER iff i=j and ordr(xi, xj) = GEASTER iff i=j and ordr(xi, xj) = DR. Compare(i, j). A list of representatives for the equivalence classes of xs under ordering ordr can be

List.map List.hd (eqclasses ordr xs) obtained by

LOCATION

Module Location

Location -- error reporting for mosmllex and mosmlyac Based on src/compiler/location from the Caml Light 0.6 distribution one the last errLocation : string * BasicIO.instream * Lexing.lexbuf -> Location -> unit : string * BasicIO instream * Lexing.lexbuf -> Location datatype Location = Source file positions
Loc of int Position of the first character
* int Position of the character following valerrPrompt: string -> 'string -> 'a valuation -> string -> 'a valuation -> string -> 'a valuation -> 'string -> 'a valuation -> 'string -> 'a valuation -> 'a valuation -> 'a valuation -> 'a valuation -> 'a -> 's valuation -> 's -> 's valu val errMsg

and parsers mosml/examples/lexyacc/ contains an example of their use. These functions support error reporting in lexers an generated with mosmllex and mosmlyac. The directory

[errLocation (file, stream, lexbuf) loc] prints the part of the lexer input which is indicated by location loc.

If file <> "" then it is assumed to be the name of the file from which the lexer reads, the stream is assumed to be an open input stream associated with this file, and lexbuf is the lexer buffer used to read from the stream. Under MS DOS (and presumably Windows, OS/2, and MacOS), the stream must have been opened in binary mode (with Nonstdio.open_in_bin), or else the positioning the file will be wrong (due to the translation of CRLF into newline in text files).

If file = "" then the lexer is assumed to read from some source other than a stream, and the lexbuf (rather than the instream) is used to obtain the location indicated, if possible. In this case the stream is immaterial, it will not be used.

[errMsg (file, stream, lexbuf) loc msg] calls errLocation to print the indicated part of the lexer input, then prints the error the indicated part of the lexer input, message msg and raises exception Fail.

on [errPrompt msg] prints "! ", the string msg, and a newline

[nilLocation] is the undefined location.

[getCurrentLocation ()] can be called within the semantic action part of a grammar rule (only) and returns the location of the string matching the left-hand side of the rule.

[mkLoc a] can be called within the semantic action part of a grammar rule (only), and returns a pair (loc, a) of the current location and the value a. This is typically used to decorate abstract syntax tree nodes with location information, for use in

[xLR loc_a] returns the location of the decorated value loc_a

[xL loc_a] returns the left end position of loc_a.

[xxIR loc_a loc_b] returns the location extending from the left end of loc_a to the right end of loc_b.

66 LOCATION

[xxRL loc_a loc_b] returns the location extending from the right end of loc_a to the left end of loc_b.

Module Math

MATH

Math -- SML Basis Librarytype real = realval pi: realval sin: real -> realval sin: real -> realval sin: real -> realval cos: real -> realval atan: real -> realval pow: real -> realval ln: real -> realval loglo: real -> realval sinh: real -> realval cosh: real -> real

[pi] is the circumference of the circle with diameter 1, that is, 3.14159265358979323846.

[e] is the base of the natural logarithm: 2.7182818284590452354.

[sqrt x] is the square root of x. Raises Domain if x < 0.0.

[sin r] is the sine of r, where r is in radians.

[cos r] is the cosine of r, where r is in radians.

[tan r] is the tangent of r, where r is in radians. Raises Domain if r is a multiple of $\mathrm{pi}/2$.

[atan t] is the arc tangent of t, in the open interval] $\neg pi/2$, pi/2 [. [asin t] is the arc sine of t, in the closed interval [$\neg pi/2$, pi/2]. Raises Domain if abs x > 1.

[acos t] is the arc cosine of t, in the closed interval [0, pi]. Raises Domain if abs x > 1.

[atan2(y, x)] is the arc tangent of y/x, in the interval] ~pi, pi], except that atan2(y, 0) = sign y * pi/2. The quadrant of the result is the same as the quadrant of the point (x, y). Hence sign(cos(atan2(y, x))) = sign y. and sign(sin(atan2(y, x))) = sign y.

[exp x] is e to the x'th power.

[pow (x, y)] is x it the y'th power, defined when y >= 0 and (y integral or x >= 0) or y < 0 and ((y integral and x <> 0.0) or x > 0).

We define pow(0, 0) = 1.

[In x] is the natural logarithm of x (that is, with base e). Raises Domain if x <= 0.0.

[log10 x] is the base-10 logarithm of x. Raises Domain if x <= 0.0.

[sinh x] returns the hyperbolic sine of x, mathematically defined as (exp x - exp (-x)) / 2. Raises Overflow if x is too large.

[cosh x] returns the hyperbolic cosine of x, mathematically defined as (exp x + exp (-x)) / 2. Raises Overflow if x is too large.

68 MATH

[tanh x] returns the hyperbolic tangent of x, mathematically defined as (sinh x) / (cosh x). Raises Domain if x is too large.

META

Module Meta

Meta -- functions available only in interactive Moscow ML sessions

These values and functions are available in the Moscow ML interactive system only.

[printVal e] prints the value of expression e to standard output exactly as it would be printed at top-level, and returns the value of e. Output is flushed immediately. This function is provided as a simple debugging aid. The effect of printVal is similar to that of 'print' in Edinburgh ML or Umeaa ML. For string arguments, the effect of SML/NU print can be achieved by the function Textlo.print : string -> unit.

[printDepth] determines the depth (in terms of nested constructors, records, tuples, lists, and vectors) to which values are printed by the top-level value printer and the function printVal. The components of the value whose depth is greater than printDepth are printed as '#'. The initial value of printDepth is 20. This value can be changed at any moment, by evaluating, for example, printDepth := 17;

[printLength] determines the way in which list values are printed by the top-level value printer and the function printVal. If the length of a list is greater than printLength, then only the first printLength elements are printed, and the remaining elements are printed as '...'. The initial value of printLength is 200. This value can be changed at any moment, by evaluating, for example, printLength := 500;

[quit ()] quits Moscow ML immediately.

(installPP pp) installs the prettyprinter pp: ppstream -> ty -> unit at type ty. The type ty must be a nullary (parameter-less) type constructor representing a datatype, either built-in (such as bool) or user-defined. Whenever a value of type ty is about to be printed by the interactive system, or function printVal is invoked on an argument of type ty, the pretty-printer pp will be invoked to print it. See library unit PP for more information.

[use "f"] causes ML declarations to be read from file f as if they were entered from the console. A file loaded by use may, in turn, evaluate calls to use. For best results, use 'use' only at top

70

top level within a use'd file. at or level, [liberal ()] sets liberal mode for the compilation functions: accept (without warnings) all extensions to the SML Modules language. The extensions are: higher-order modules (functors defined within structures and functors); first-order modules (structures can be packed as values, and values can be unpacked as structures); and recursively defined modules (signatures and structures). The liberal, conservative, and orthodox modes affect the functions compile, compileStructure, and compileToplevel. The iberal mode may be set also by the mosml option -liberal.

[conservative ()] sets conservative mode for the compilation functions: accept all extensions to the SML Modules language, but issue a warning for each use. The conservative mode may be set also by the mostin option -conservative. This is the default.

[orthodox ()] sets orthodox mode for the compilation functions: reject all uses of the extensions to the SML Modules language. That is, accept only SML Modules syntax. The orthodox mode may be set also by the mosml option -orthodox.

compile "U.sig"] will compile and elaborate the specifications in file U.sig in structure mode, producing a compiled signature U in file U.ui. This function is backwards compatible with Moscow ML 1.44 and earlier. Equivalent to compileStructure [] "U.sig". [compile "U.sml"] will elaborate and compile the declarations in file U.sml in structure mode, producing a compiled structure U in bytecode file U.u.o. If there is an explicit signature file U.sig, then file U.ui must exist, and the unit body must match the signature. If there is no U. sig, then an inferred signature file U.ui will be produced also. No evaluation takes place. This function is backwards compatible with Moscow ML 1.44 and earlier. Equivalent to compileStructure [] "U.sml" The declared identifiers will be reported if verbose is true (see below); otherwise compilation will be silent. In any case, compilation warnings are reported, and compilation errors abort the compilation and raise the exception Fail with a string argument.

[compileStructure opnumits "U.sig"] compiles the specifications in file U.sig as if they form a signature declaration signature U = sig ... contents of U.sig ... end The contents of opnumits is added to the compilation context in which the specifications in U.sig are compiled. The result is a compiled signature file U.ui. This corresponds to invoking the batch compiler as follows: mosmlc -C ul.ui ... Un.ui -structure U.sig where opnumits equals ["U1", ..., "Un"].

compileStructure opnunits "U.sml"] compiles the declarations in file U.sml as if they formed a structure declaration

structure U = struct... contents of U.sml ... end
The contents of opmunits is added to the compilation context in
which the declarations in U.sml are compiled. If U.ui exists
already and represents a signature called U, then the compiled
declarations are matched against it. The result is a bytecode file
U.uo. If no file U.ui existed, then also a file U.ui is created,
containing the inferred signature of structure U. This
corresponds to invoking the batch compiler as follows:
mosmlc -c Ul.ui ... Un.ui -structure U.sml

mosmic -c Ui.ui ... Un.ui -st where opnunits equals ["Ul", ...,

Ľ. [compileToplevel opnumits "U.sig"] compiles the specifications in file U.sig, in a context in which all declarations from opnumits are visible, creating a compiled signature file U.ui. This corresponds to invoking the batch compiler as follows: mosmic -c Ul.ui ... Un.ui -toplevel U.sig

mosmlc -c עו.טו ייי טח.עז -נט. שאhere opnunits equals ["Ul", ...,

compileToplevel opnunits "U.sml"] compiles the declarations in

META META

This corresponds to invoking the context in which all declarations from opnunits are visible, creating a bytecode file U.uo. If U.ui exists already, then the compiled declarations are matched against it; otherwise the file U.ui is created. This corresponds to invoki

Un.ui -toplevel U.sml 11", ..., "Un"]. batch compiler as follows mosmlc -c Ul.ui ... Un.ui -to where opnunits equals ["Ul", ..., [load "U"] will load and evaluate the compiled unit body from file U.uo. The resulting values are not reported, but exceptions are reported, and cause evaluation and loading to stop. If U is already loaded, then load "U" has no effect. If any other unit is mentioned by U but not yet loaded, then it will be loaded automatically before U.

Opening it top-level will list the identifiers declared in the unit can be opened with 'open U' After loading a unit, it

When loading U, it is checked that the signatures of units mentioned by U agree with the signatures used when compiling U, and it is checked that the signature of U has not been modified since U was compiled; these checks are necessary for type safety. The exception Fall is raised if these signature checks fall, or if the file containing U or a unit mentioned by U does not exist.

[loadone "U"] is similar to 'load "U", but raises exception Fail if U is already loaded or if some unit mentioned by U is not yet loaded. That is, it does not automatically load any units mentioned by U. It performs the same signature checks as 'load'.

[loaded ()] returns a list of the names of all compiled units that have been loaded so far. The names appear in some random order.

[loadbath] determines the load path: which directories will be searched for interface files (.ui files), bytecode files (.uo files), and source files (.sml files). This variable affects the load, loadone, and use functions. The current directory is always searched first, followed by the directories in loadpath, in order. By default, only the standard library directory is in the list, but if additional directories are specified using option -1, then these directories are prepended to loadPath. [quietdec] when true, turns off the interactive system's prompt and responses, except warnings and error messages. Useful for writing scripts in SML. The default value is false; can be set to true with the -quietdec command line option.

[verbose] determines whether the signature inferred by a call to compile will be printed. The printed signature follows the syntax of Moscow ML signatures, so the output of compile "U.sml" can be edited to subsequently create file U.sig. The default value is false

ML symbolic identifiers. When quotation is true, the backguote character is illegal in symbolic identifiers, and a quotation ab c'will be recognized by the parser and evaluated to an object of type 'a General.frag list. False by default. [quotation] determines whether quotations and antiquotations are permitted in declarations entered at top-level and in files compiled with compile. A guotation is a piece of text surrounded by backquote characters 'a b c' and is used to embed object language phrases in ML programs; see the Moscow ML Owner's Manual for a brief explanation of quotations. When quotation is false, the backquote character is an ordinary symbol which can be used in

[valuepoly] determines whether value polymorphism is used or not in the type checker. With value polymorphism (the default), there is no distinction between imperative ('a) and applicative ('a) type variables, and type variables are generalized only in bindings to variables, and expressions. Non-generalized type variables are left free, to be instantiated when the bound identifier is used. An expression is non-expansive if it is a variable, a special

72 META

constant, a function, a tuple or record of non-expansive expressions, a parenthesized or typed non-expansive expression, or the application of an exception or value constructor (other than ref) to a non-expansive expression. If valuepoly is false, then the type checker will distinguish imperative and applicative type variables, generalize all applicative type variables, and generalize imperative type variables only in non-expansive expressions. True by default.

a tuple or record of non-expansive thesized or typed non-expansive sxpression, or assertion or value constructor (other than

MOSML

Module Mosml

Mosml -- some Moscow ML specific functions

```
val argv : unit -> string list
val listDi : ('a -> 'b) -> ('a -> 'b)
val listDi : string -> string list
val doubleVec : real -> Word8Vector.vector
val vecDouble : Word8Vector.vector -> real
val floatVec : real -> Word8Vector.vector
val vecFloat : Word8Vector.vector
val wecFloat : Word8Vector.vector
val mdSsum : string -> string
datatype runresult =
   Success of string
| Failure of string
val run : string -> string list -> string -> runresult
val run : string -> string -> string -> val runsevalt
```

[argv ()] returns the command line strings of the current process. Hence List.nth(argv (), 0) is the command used to invoke the SML process, List.nth(argv (), 1) is its first argument, and so on. We recommend using the SML Basis Library Commandine structure instead.

[time f arg] applies f to arg and returns the result; as a side effect, it prints the time (cpu, system, and real time) consumed by the evaluation.

[listDir path] returns the list of all files and subdirectories of the directory indicated by path. Raises OS.SysErr in case of failure.

[doubleVec r] returns an eight-element vector of Word8.word, which contains the real number in the IEEE 754 floating-point 'double format' bit layout stored in big-endian (high byte first) order.

[vecDouble v] accepts an eight-element vector v of Word8.word, and returns the real number obtained by taking v to be an IEEE 754 floating-point 'double format' number stored in big-endian (high byte first) order. Raises Fail if v is not en eight-element vector.

[floatVec r] returns a four-element vector of Words.word, which contains the real number in the IERS 754 float.layout vious torred in big-endian (high byte first) order. Raises Fail if r is not representable as a 32-bit float.

[vecFloat v] accepts a four-element vector v of Word8.word, and returns the real obtained by taking v to be an IEBE 754 floating-point 'float format' number stored in big-endian (high byte first) order. Raises Fail if v is not a four-element vector.

[md5sum s] computes the 128-bit MD5 checksum of string s and returns it as a 22 character base64 string.

[run cmd args inp] executes the program cmd with command-line arguments args and standard input inp. Returns Success s where s is the program's (standard and error) output as a string, if it executed successfully; otherwise returns Failure s where s is its (standard and error) output as a string.

The Mosmlegi library is for writing CGI programs in Moscow ML. OGI program may be installed on a WWW server and is invoked in response to HTTP requests sent to the server from a web browser, typically from an HTML FORM element.

MOSMLCGI

```
[cgi_fieldnames] is a list of the names of fields present in the CGI call message. If field name fnm is in cgi_fieldnames, then cgi_field_string fnm <> NONE.
```

```
[cgi_field_strings fnm] is a (possibly empty) list of the strings bound to field fnm.
```

```
[cgi_field_string fnm] returns SOME(s) where s is a string bound to field name fnm, if any; otherwise NONE. Equivalent to case cgi_field_strings fnm of [] => NONE
```

```
=> SOME
ω
::
```

[cgi_field_integer (fnm, deflt)] attempts to parse an integer from field fnm. Returns i if cgi_field_string(fnm) = SOME(s) and an integer i can be parsed from a prefix of s; otherwise returns deflt.

Obtaining field values sent with ENCTYPE="multipart/form-data"

```
[cgi_partnames] is a list of the names of the parts of the multipart/form-data message.
```

Each part The type part is the abstract type of parts of a message. Each p may have several fields. In this implementation, the field of a part cannot be a another part itself.

[cgi_parts pnm] is a (possibly empty) list of the parts called pnm

[ogi_part pnm] is SOWE(prt) where prt is a part called pnm, if any; otherwise NONE. Equivalent to case cgi_parts pnm_of

```
prt :: _ => SOME prt
=> NONE
```

[part_fieldnames prt] is the list of field names in part pnm.

[part_type prt] is SOWE(typ) if the part prt contains a specification 'Context-Type: typ'; otherwise NONE.

the [part_data prt] is the data contain in part prt; for instance, contents of a file uploaded via form-based file upload.

the [part_field_strings prt fnm] is a (possibly empty) list of strings bound to field fnm in part prt. [part_field_string prt fnm] returns SOME(s) where s is a string bound to field name fnm in part prt, if any; otherwise NONE. Equivalent to

```
case part_field_strings prt fnm of
                | | => NONE
| | => SOME | S
```

[part_field_integer prt (fnm, deflt)] attempts to parse an integer from field fnm of part prt. Returns i if part_field_string prt fnm = SOME(s) and an integer i can be parsed from a prefix of s; otherwise returns deflt.

Administrative and server information

Each of the following variables has the value ${\rm SOME}(s)$ if the corresponding CGI environment variable is bound to string s; otherwise ${\rm NONE}$:

[cgi_server_software] is the value of SERVER_SOFTWARE

[cgi_server_name] is the value of SERVER_NAME

Obtaining field values sent from an ordinary HTML form

76 MOSMLCGI

```
[ogi_content_length] is the value of CONTENT_LENGTH, that is, the length of the data transmitted in the CGI call.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           cgi_http_proxy_comection] is the value of HTTP_PROXY_CONNECTION
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             [cgi_annotation_server] is the value of ANNOTATION_SERVER
[cgi_gateway_interface] is the value of GATEWAY_INTERFACE
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      cgi_request_filename] is the value of REQUEST_FILENAME
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       [cgi_path_translated] is the value of PATH_TRANSLATED
                                                                                [cgi_server_protocol] is the value of SERVER_PROTOCOL
                                                                                                                                                                                                                                                                                                                                                                                                  [cgi_http_user_agent] is the value of HTTP_USER_AGENT
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       cgi_script_filename] is the value of SCRIPT_FILENAME
                                                                                                                                                                                                                                         cgi_request_method] is the value of REQUEST_METHOD
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      cgi_http_forwarded] is the value of HTTP_FORWARDED
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    [cgi_document_root] is the value of DOCUMENT_ROOT
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                [cgi_query_string] is the value of QUERY_STRING
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                cgi_server_admin] is the value of SERVER_ADMIN
                                                                                                                                                                                                                                                                                                                                                                                                                                                                              cgi_http_referer] is the value of HTTP_REFERER
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 [cgi_remote_ident] is the value of REMOTE_IDENT
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          [cgi_content_type] is the value of CONTENT_TYPE
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      [cgi_http_cookie] is the value of HTTP_COOKIE
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   cgi_script_name] is the value of SCRIPT_NAME
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 cgi_api_version] is the value of API_VERSION
                                                                                                                                                        [cgi_server_port] is the value of SERVER_PORT
                                                                                                                                                                                                                                                                                                                          [cgi_http_accept] is the value of HTTP_ACCEPT
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                [cgi_remote_host] is the value of REMOTE_HOST
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         [cgi_remote_addr] is the value of REMOTE_ADDR
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     [cgi_remote_user] is the value of REMOTE_USER
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             [cgi_the_request] is the value of THE_REQUEST
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     cgi_request_uri] is the value of REQUEST_URI
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           [cgi_path_info] is the value of PATH_INFO
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              [cgi_auth_type] is the value of AUTH_TYPE
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              [cgi_is_subreq] is the value of IS_SUBREQ
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   [cgi_http_host] is the value of HTTP_HOST
```

MOSMLCOOKIE

Module Mosmicookie

These functions may be used in CGI scripts to get and set cookies.

(c) Hans Molin, Computing Science Dept., Uppsala University, 1999. [getCookieValue ck] returns SOME(v) where v is the value associated with the cookie ck, if any; otherwise returns NONE.

[getCookie ck] returns SOME(nv) where nv is the ck-value string for the cookie ck, if any; otherwise returns NONE.

[allCookies] is a list [nv1, nv2, ..., nvm] of all the ck-value pairs of defined cookies.

[setCookie { name, value, expiry, domain, path, secure } } returns a string which (when transmitted to a browser as part of the HTTP response header) sets a cookie with the given name, value, expiry date, domain, path, and security.

[setCookies ckds] returns a string which (when transmitted to a browser as part of the HTTP response header) sets the specified cookies.

[deleteCookie { name, path }] returns a string which (when transmitted to a browser as part of the HTTP response header) deletes the specified cookie by setting its expiry to some time in

```
[N1] represents the string "\n" consisting of a single newline character.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              In general, multiple strings may be associated with a CGI parameter; use Mosmlcgi.cgi_field_strings if you need to access all of them.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          [%# fnm] returns the integer i if there is a string associated with CGI parameter fnm, and that string is parsable as ML integer i. Staises ParamMissing(fnm) if no string is associated with fnm. Raises NotInt(fnm, s) if there is a string but it is not parsable as an ML int.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                [% frm] returns a string associated with CGI parameter fnm if there is any: raises ParamMissing(fnm) if no strings are associated with fnm.                                                                                                                                                                                                                                                                                                                                                                                                                                                 This module provides support functions for writing CGI scripts and {\rm ML} Server Page scripts.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 \{\$\$\#(fnm,\ dflt)\} returns the integer i if there is a string associated with CGI parameter fnm, and that string is parsable as
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     [wseq] is the type of efficiently concatenable word sequences. Building an HTML page (functionally) as a wseq is more efficient than building it (functionally) as a string, and more convenient and modular than building it (imperatively) by calling print.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               [prmap f xs] is f xl && ... && f xn evaluated from left to right when xs is [x1, ..., xn].
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   [prsep sep f xs] is f x1 && sep && ... && sep && f xn, evaluated from left to right, when xs is [x1, ..., xn].

The function && should be declared
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            [%%(fnm, dflt)] returns a string associated with CGI parameter if there is any; otherwise returns the string dflt.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               [%? fnm] returns true if there is a string associated with CGI parameter fnm; otherwise returns false.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          [printseq ws] is equivalent to print(flatten ws), but avoids building any new strings.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           [vec2list vec] is a list of the elements of vector vec. Us convert e.g. the results of a database query into a list, sprocessing with prmap or prsep.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     [$$ ss] represents the string String.concat(ss).
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            [flatten ws] is the string represented by ws.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 ''y ta.co. ---

```
HTML forms etc:
```

[form act ws] generates <FORM ACTION="act">ws</FORM>

[forma act attr ws] generates <FORM ACTION="act" attr>ws</FORM>.

generates <INPUT TYPE=typ> [input typ] [inputa typ attr] generates <INPUT TYPE=typ attr>.

[intext name attr] generates <INPUT TYPE=TEXT NAME="name" attr>.

[inpassword name attr] generates <INPUT TYPE=PASSWORD NAME="name" attr>.

[incheckbox {name, value} attr] generates
<INPUT TYPE=CHECKBOX NAME="name" VALUE="value" attr>.

[inradio {name, value} attr] generates
<INPUT TYPE=RADIO NAME="name" VALUE="value" attr>.

[insubmit value attr] generates <INPUT TYPE=SUBMIT VALUE="value" attr>.

[inreset value attr] generates <INPUT TYPE=RESET VALUE="value" attr>.

[inhidden {name, value}] generates
<INPUT TYPE=HIDDEN NAME="name" VALUE="value">.

[textarea name ws] generates <TEXTAREA NAME="name">ws</TEXTAREA>.

[textareaa name attr ws] generates <TEXTAREA NAME="name" attr>ws</TEXTAREA>.

[select name attr ws] generates <SELECT NAME="name" attr>ws</SELECT>

[option value] generates <OPTION VALUE="value">.

HTML frames and framesets:

[frameset attr ws] generates <FRAMESET attr>ws</FRAMESET>.

[frame { src, name }] generates <FRAME SRC="src" NAME="name">.

[framea { src, name } attr] generates <FRAME SRC="src" NAME="name" attr>.

HTML encoding functions:

[urlencode s] returns the url-encoding of s. That is, space (ASCII 32) is replaced by '+' and every non-alphanumeric character c except the three characters hyphen (-), underscore (_) and full stop (.) is replaced by %th, where th is the hexadecimal representation of the ASCII code of c.

[htmlencode s] returns the html-encoding of s. That is, < and > are replaced by < and > respectively, and & is replaced by &

The result is a connection which may be used in subsequent queries. In MySQL, unlike PostgreSQL, the dboptions and dbtty fields are not used.

status dbconn] returns true if the connection is usable, false

reset dbconn] attempts to close and then reopen the connection the database server. [errormessage dbconn] returns NONE if no error occurred, and SOME msg [f an error occurred, where msg describes the error. if an error occurred,

[execute dbconn query] sends an SQL query to the database server for execution, and returns a resultset dbres.

[resultstatus dbres] returns the status of the result set dbres. After a select query that succeeded, it will be Tuples_ok

ntuples dbres] returns the number of tuples in the result set after a query.

condruples dbres] returns the number of tuples affected by an insert, update, or delete SQL command.

nfields dbres] returns the number of fields in each tuple after

[fname dbres fno] returns the name of field number fno (in the result set after a query). The fields are numbered 0, 1,... result set after a query). fnames dbres] returns a vector of the field names (in the result set after a query). [fnumber dbres fname] returns SOME i where i is the number (0, 1, ...) of the field called fname (in the result set after a query), if the result set contains such a field name; returns NOME otherwise.

returns the dyntype of field number fno (in the [ftype dbres fno] returns 'result set after a query). [ftypes dbres] returns a vector of the dyntypes (in the result set after a query). after

getint dbres fno tupnol returns the integer value of field number ino in tuple tupno of result set dbres. Raises Null if the value [fromtag dt] returns the name of the preferred MySQL type used to represent values of the dyntype dt. This may be used when building 'create table' statements. is NULL. fno

[getreal dbres fno tupno] returns the floating-point value of field number fno in tuple tupno of result set dbres. Raises Null if the value is NULL.

[getstring dbres fno tupno] returns the string value of field number fno in tuple tupno of result set dbres. Raises Null if the value is NULL.

[getdate dbres fno tupno] returns the date (yyyy, mth, day) value of field number fno in tuple tupno of result set dbres. Raises Null if the value is NULL. Raises Fail if the field cannot be scanned as a date.

[gettime dbres fno tupno] returns the time-of-day (hh, mm, ss) value of field number fno in tuple tupno of result set dbres. Raises Null if the value is NULL. Raises Fail if the field cannot be scanned as a time.

[getdatetime dbres fno tupno] returns the Date.date value of field number fno in tuple tupno of result set dbres. Raises Null if the value is NULL. Raises Fail if the field cannot be scanned as a date.

[getbool dbres fno tupno] returns the boolean value of field number fno in tuple tupno of result set dbres. Raises Null if the value is NULL.

[getdynfield dbres fno tupno] returns the value of field number fno in tuple tupno of result set dbres as a dayval (a wrapped value). A NULL value is returned as NullVal. Note that the partial application (getdynfield dbres fno) precomputes the type of the field fno. Hence it is far more efficient to compute in tabulate(ntuples dbres, getfno) end [isnull dbres fno tupno] returns true if the value of field number fno in tuple tupno of result set dbres is NULL; false otherwise.

than to compute

let fun getfno tupno = getdynfield dbres fno tupno
in tabulate(ntuples dbres, getfno) end

because the latter repeatedly computes the type of the field.

[getdyntup dbres tupno] returns the fields of tuple tupno in result dbres as a vector of dynvals.

[getdyntups dbres] returns all tuples of result set dbres as vector of vectors of dynvals.

[dynval2s dv] returns a string representing the dynval dv.

[applyto x f] computes f(x). This is convenient for applying several functions (given in a list or vector) to the same value: map (applyto 5) (tabulate(3, getdynfield dbres))

[getdynfield dbres 0 5, getdynfield dbres 1 5, getdynfield dbres 2 5]

[copytableto(dbconn, tablename, put)] simulates a PostgreSQL "COPY TABLE TO" statement, applies the function put to every tuple of the table. represented as a line of text (not terminated by newline \n), and cleans up at the end. For instance, to copy the contents of a table t to a text stream s (one tuple on each line), define fun put line = fun put line; TextIO.output(s, line); TextIO.output(s, "\n"))

and execute copytableto(dbconn, "t", put).

[copytablefrom(dbconn, tablename, useput)] simulates a PostgreSQL "COPY TABLE FROW" statement, creates a put function for copying lines to the table, passes the put function to useput, and cleans up at the end. The put function may be called multiple times for each line (tuple); the end of each line is indicated by the newline character "\n" as usual. For instance, to copy the contents of a text stream s to a table t, define fun useput put =

while not (TextIO.endOfStream s) do put(TextIO.inputLine s). and execute

Note that TextIO.inputLine preserves the newline at the end of each copytablefrom(dbconn, "t", useput)

[formattable dbresult] returns a wseq representing an HTML table. The HTML table has a column for every field in the dbresult. The first row is a table header giving the names of the fields in the dbresult. The remaining rows correspond to the tuples in the dbresult, in the order they are provided by the database server. Null fields are shown as NULL.

[showquery dbconn query] sends the SQL query to the database server, then uses formattable to format the result of the query.

This structure provides tools for creating customized Oppen-style pretty-printers, based on the type pystream. A pystream is an output stream that contains prettyprinting commands. The commands are placed in the stream by various function calls listed below.

There following primitives add commands to the stream: begin_block, end_block, add_string, add_break, and add_newline. All calls to add_string, add_break, and add_newline must happen between a pair of calls to begin_block and end_block must be properly nested dynamically. All calls to begin_block and end_block and

Jo [ppconsumer] is the type of sinks for pretty-printing. A value of type ppconsumer is a record { consumer : string -> unit, { linewidth : int, | nint, > unit } } of a string consumer, a specified linewidth, and a flush function which is called whenever flush_ppstream is called.

addition, a prettyprinter for a base type or mullary datatype ty can be installed in the top-level system. Then the installed prettyprinter will be invoked automatically whenever a value of type ty is to be printed. A prettyprinter can be called outright to print a value. In

[break_style] is the type of line break styles for blocks:

the [CONSISTENT] specifies that if any line break occurs inside block, then all indicated line breaks occur.

[mk_ppstream {consumer, linewidth, flush}] creates a new ppstream
which invokes the consumer to output text, putting at most
linewidth characters on each line. ಭ specifies that breaks will be inserted to only lines. [INCONSISTENT]
avoid overfull

dest_ppstream ppstrm] extracts the linewidth, flush function, and

consumer from a postream.

[add_break ppstrm (size, offset)] notifies the pretty-printer that a line break is possible at this point.
* When the current block style is CONSISTENT:
** if the entire block fits on the remainder of the line, then output size spaces; else
** increase the current indentation by the block offset;

4

```
further indent every item of the block by offset, and add one newline at every add_break in the block.

* When the current block style is INCONSISTENT:

** if the next component of the block fits on the remainder of the line, then output size spaces; else

** issue a newline and indent to the current indentation level plus the block offset plus the offset.
```

[add_newline ppstrm] issues a newline.

[add_string ppstrm str] outputs the string str to the ppstream.

[begin_block ppstrm style blockoffset] begins a new block and level of indentation, with the given style and block offset.

[end_block ppstrm] closes the current block.

[clear_ppstream ppstrm] restarts the stream, without affecting the underlying consumer.

[flush_ppstream ppstrm] executes any remaining commands in the ppstream (that is, flushes currently accumulated output to the consumer associated with ppstrm); executes the flush function associated with the consumer; and calls clear_ppstream.

[with pp consumer f] makes a new ppstream from the consumer and applies f (which can be thought of as a producer) to that ppstream, then flushed the ppstream and returns the value of f.

[pp_to_string linewidth printit x] constructs a new ppstream ppstrm whose consumer accumulates the output in a string s. Then evaluates (printit ppstrm x) and finally returns the string s.

Example 1: A simple prettyprinter for Booleans:

```
begin_block pps INCONSISTENT 6;
add_string pps (if d then "right" else "wrong");
end_block pps
       fun ppbool pps d = let open PP
load "PP";
```

Now one may define a ppstream to print to, and exercise it:

```
fn () => TextIO.flushOut TextIO.stdOut};
fun ppb b = (ppbool ppstrm b; PP.flush_ppstream ppstrm);
                                                                                                                    wrong val it = () : unit
                                                                                                         - ppb false;
```

The prettyprinter may also be installed in the toplevel system; than it will be used to print all expressions of type bool subsequently computed:

```
- installPP ppbool;
> val it = () : unit
- 1=0;
> val it = wrong : bool
```

- 1=1; > val it = right : bool

See library Meta for a description of installPP.

PPPP Example 2: Prettyprinting simple expressions (examples/pretty/ppexpr.sml):

```
val el = Cst 1;
val e2 = Cst 2;
val e2 = Lus(el, Neg e2);
val e3 = Plus(Neg e3, e3);
val e5 = Plus(Neg e4, e4);
val e6 = Plus(e6, e5);
val e7 = Plus(e6, e6);
val e8 = Plus(e3, Plus(e3, Plus(e3, Plus(e3, e7))))));
                                                                                 ppe e1;
add.string pps " + ";
add.break pps (0, 1);
ppe e2;
add.string pps ")";
end_block pps)
                                                                                                                                                                                                                                                             begin_block pps INCONSISTENT 0;

PARSING 96

Module Parsing

Parsing -- runtime library for parsers generated by mosmlyac Based on the runtime library for camlyacc; copyright 1993 INRIA, France

local open Vector Obj Lexing in

val symbolStart : unit -> int val symbolEnd : unit -> int val itemStart : int -> int val itemEnd : int -> int val clearParser : unit -> unit

For internal use in generated parsers:

(unit -> obj) vector type parseTables =

int vector is string * int * string * s gindex tablesize actions transl lhs len defred dgoto sindex rindex table check exception yyexit of obj
exception ParseError of (obj -> bool)

val yyparse : parseTables -> int -> (lexbuf -> 'a) -> lexbuf -> 'b
val peekVal : int -> 'a

end

For These functions are for use in mosmlyac-generated parsers. For further information, see the Moscow ML Owner's Manual. For examples, see mosml/examples/lexyacc and mosml/examples/calc. A grammar definition (input to mosmlyac) consists of fragments of this form

{ action1 } action2 } grsyms2 grsyms3 grsymsl nonterm:

where the grsyms are sequences of grammar symbols, matching some string of characters, and the actions are corresponding semantic actions, written in ML. The following functions can be used in the semantic actions:

ij. [symbolStart ()] returns the start position of the string that matches the sequence of grammar symbols. The first character ithe input stream has position 0. May be called in a semantic action only. [symbolEnd ()] returns the end position, plus one, of the string that matches the sequence of grammar symbols. The first character in the input stream has position 0. May be called in a semantic action only.

[itemStart i] returns the start position of the string that matches then i'th grammar symbol in the sequence. The first grammar symbol has number 1. The first character in the input stream has position 0. May be called in a semantic action only.

PARSING

[itemEnd i] returns the end position, plus one, of the string that matches the i'th grammar symbol in the sequence. The first grammar symbols has number 1. The first character in the input stream has position 0. May be called in a semantic action only.

[clearParser ()] clears the parser stack. It may be called after a parsing function has returned, to remove all pointers from the parser stack to structures that were built by semantic actions during parsing. This is not strict necessary, but reduces the memory requirements of the program.

This module provides OS-independent functions for manipulating strings that represent file names and paths in a directory structure. None of these functions accesses the actual filesystem.

Definitions:

* An arc denotes a directory or file. Under Unix or DOS, an arc may have form "..., ".", "", or "abc", or similar.

* An absolute path has a root: Unix examples include "/", "/a/b"; DOS examples include "\", "\a\b", "A:\a\b".

* A relative path is one without a root: Unix examples include "..", "a/b"; DOS examples include "..", "a\b", "A:a\b".

* A path has an associated volume. Under Unix, there is only one volume, whose name is "". Under DOS, the volume names are "", "A:", "C:", and similar.

* A canonical path contains no occurrences of the empty arc "" or the current arc ".", and contains or the parent arc ".." only at the beginning and only if the path is relative. \star All functions (except concat) preserve canonical paths. That is, if all arguments are canonical, then so will the result be.

* All functions are defined so that they work sensibly on canonical

* There are three groups of functions, corresponding to three ways to look at paths, exemplified by the following paths:

Unix: d/e/f/a.b.c and /d/e/f/a.b.c DOS: A:d/e/f/a.b.c and A:d/e/f/a.b.c

A path consists of a sequence of arcs, possibly preceded by volume and a root:

PATH

' I	A: (d e f a.b. A: (d e f a.b.
vol [arcs]	nix examples: d e f a.b.c OS examples: A: d e f a.b

(2) A path consists of a directory part and a (last) file name part:

file	a a.b.c
directo	/d/e/f A:\d\e\f
file	a.b.c
rectory	d/e/f A:d\e\f
	Unix examples: DOS examples:

(3) A path consists of a base and an extension:

ensio	<u>၂</u> ပ ည	
base	/d/e/f/a.b A:\d\e\f\a	
extension	p,q	
base	d/e/f/a.b A:d\e\f\a	
	Unix examples: DOS examples:	

GROUP 0: General functions on paths:

[parentArc] is the arc denoting a parent directory: ".." under DOS and Unix.

[currentArc] is the arc denoting the current directory: "." under ${\sf DOS}$ and ${\sf Unix}$.

[isRelative p] returns true if p is a relative path.

[isAbsolute p] returns true if p is an absolute path Equals not (isRelative p).

[validVolume {isAbs, vol}] returns true if vol is a valid volume name for an absolute path (if isAbs=true) resp. for a relative path (if isAbs=false). Under Unix, the only valid volume name is "", under MS DOS and MS Windows the valid volume names are "", "a:", "b:", ..., and "A:", "B:", ...

[getParent p] returns a string denoting the parent directory of p. It holds that getParent p = p if and only if p is a root.

[concat (p1, p2)] returns the path consisting of p1 followed by p2. Does not preserve canonical paths: $\operatorname{concat}("a/b", "../c")$ equals $\operatorname{ad}(b,...,r)$. This is because "a/b/../c" and "a/c" may not be equivalent in the presence of symbolic links. Raises Path if p2 is not a relative path.

[mkAbsolute { path=pl, relativeTo=p2 }] returns the absolute path made by taking path p2, then pl. That is, returns p1 if pl is absolute; otherwise returns the canonicalized concatenation of p2 and pl. Raises Path if p2 is not absolute (even if pl is absolute).

[mkRelative { path=pl, relativeTo=p2 }] returns pl relative to p2. That is, returns pl if pl is already relative; otherwise returns the relative path leading from p2 to pl. Raises Path if p2 is not absolute (and even if pl is relative), or if pl and p2 are both absolute but have different roots.

[mkCanonical p] returns a canonical path which is equivalent to p. Redundant occurrences of the parent arc, the current arc, and the empty arc are removed. The canonical path will never be the empty string; the empty path is converted to the current directory path ("." under Unix and DOS).

[isCanonical p] is equal to (p = mkCanonical p).

PATH 100

GROUP 1: Manipulating volumes and arcs:

[fromString p] returns {isAbs=false, vol, arcs} if the path p is relative, and {isAbs=true, vol, arcs} if the path p is absolute. In both cases vol is the volume name and arcs is the list of (possibly empty) arcs of the path. Under Unix, the volume name is always the empty string ""; under DOS it will have form "A:", "C:", or similar. [toString path] reconstitutes a path from its root (if any) and area. Raises Path if applied to a relative path whose first arc is empty. It holds that toString(fromString p) = p, except that in MS DOS, slashes "\" in p will be replaced by backslashes "\" if holds that fromString (toString p) = p when no exception is raised. It holds that isRelative(toString p) = p when no exception is raised, when no exception is raised.

[getVolume p] returns the volume name of the path p, if given. Under Unix and MacOS, this is always the empty string "", and under MS DOS and MS Windows, it may have form "A:", "B:", ...

GROUP 2: Manipulating directory paths and file names:

[splitDirFile p] returns {dir, file} where file is the last arc in p, and dir is the path preceding that arc. A typical use is to split a path into the directory part (dir) and the filename (file).

[joinDirFile {dir, file}] returns the path p obtained by extending the path dir with the arc file.

[dir p] equals #dir (splitDirFile p).

[file p] equals #file (splitDirFile p).

GROUP 3: Manipulating file names and extensions:

[splitBaseExt s] returns {base, ext} where ext = NONE if s has no extension, and ext = SOME e if s has extension e; base is the part of s precedding the extension a sis considered having no extension if its last arc contains no extension separator (typically ".") or contains an extension separator only as its feftwost character, or contains an extension separator as its right-most character. Hence none of "a.b/cd", "a/.login", "a.", ".". ". "and "." has an extension.

[joinBaseExt {base, ext}] returns an arc composed of the base name and the extension (if different from NONE). It is a left inverse of splitBaseExt, so joinBaseExt (splitBaseExt s) = s, but the opposite does not hold (since the extension may be empty, or may contain extension separators).

ext s] equals #ext (splitBaseExt s).

[base s] equals #base (splitBaseExt s).

POLYGDBM

Module Polygdbm

-- requires Dynlib Polygdbm -- GNU gdbm persistent polymorphic hashtables

type ('key, 'data) table

exception NotFound exception AlreadyThere exception NotWriter

Closed exception

exception GdbmError of string

val withtable val add val insert

insert find peek hasKey

remove listKeys numItems listItems

map fold val val val val val

ر ر

^

'data | table -> unit bool ref val reorganize : ('key, fastwrite

[('key, 'data) table] is the type of an opened table with keys of type 'key and associated values of type 'data. The actual values of type 'key and 'data cannot contain function closures or abstract values. Values involving references (even circular values) can be stored, but the identity of references is preserved only with every single key or value stored, not across several different values.

The Polygdbm table files of are not portable across platforms, because word size and endianness affects the lay-out of values.

A value of type table can be used only in the argument f to the withtable function. This makes sure that the table is closed after

[withtable (nam, mod) f] first opens the table db in file nam with mode mod, then applies f to db, then closes db. Makes sure to close db even if an exception is raised during the evaluation of f(db). Raises GdbmError with an informative message in case the table cannot be opened. Eq. the table cannot be opened for reading if already opened for writing, and cannot be opened for writing if already opened for reading.

[add db (k,v)] adds the pair (k,v) to db. Raises AlreadyThere if there is a pair $(k, _)$ in db already. Raises NotWriter if db is not opened in write mode.

[insert db (k, v)] adds the pair (k, v) to db, replacing any pair (k, _) at k if present. Raises NotWriter if db is not opened in write mode.

[find(db, k)] returns v if the pair (k, v) is in db; otherwise raises NotFound

otherwise pair (k, v) is in db; returns SOME v if the returns NONE db k]

[hasKey(db, k)] returns true if there is a pair $(k, _)$ in otherwise returns false. [remove db k] deletes the pair $(k, \)$ from the table if present; otherwise raises NotFound. Raises NotWriter if db is not opened in write mode.

POLYGDBM 102

unspecified an i, ф 'n. [listKeys db] returns a list of all keys

ą [numItems db] is the number of (key, value) pairs in Equivalent to length(listKeys db).

some i. ф [listItems db] returns a list of all (key, value) pairs in order. Equivalent to List.map (fn key => (key, find(db,key))) (listKeys db)

the [app f db] is equivalent to List.app f (listItems db), provided function f does not change the set of keys in the table.

Otherwise the effect is unpredictable. [map f db] is equivalent to List.map f (listItems db), provided the function f does not change the set of keys in the table.
Otherwise the result and effect are unpredictable.

[fold f a db] is equivalent to List.foldr (f ((k, v, r) = (k, v, r)) a (listItems db) provided the function f does not change the set of keys in the table. Otherwise the result and effect are unpredictable.

[fastwrite] can be set to speed up writes to a table. By default, ifsatwrite is false and every write to a table will be followed by file system synchronization. This is safe, but slow if you perform thousands of writes. However, if ifsatwrite is true when calling which then writes may not be followed by synchronization, which may speed up writes considerably. In any case, the file system is synchronized before withtable returns.

[reorganize db] has no visible effect, but may be called after a lot of deletions to shrink the size of the table file.

POLYHASH

Module Polyhash

SML/NJ Library Polyhash -- polymorphic hashtables as in the

'data) hash_table type ('key,

->'_data_option
:('key, 'data) hash_table -> 'key -> 'data
:('key, 'data) hash_table -> 'key -> 'data option
:('key, 'data) hash_table -> 'key -> 'data
:('key, 'data) hash_table -> ('key * 'data) list
:('key, 'data -> unit) -> ('key, 'data) hash_table -> val copy : (' key, ' data) hash_table -> (' key, '_data) hash_table
val bucketSizes : ('key, 'data) hash_table -> int list : (',key -> int) * (',key * ',key -> bool) -> int * exr -> (',key, ',data) hash_table : ('key, 'data) hash_table -> int ',key ',data) hash_table -> ',key * ',data : (',key, ',data) hash_table -> ',key * ',data -> unit : (',key, ',data) hash_table -> ',key * ',data val insert val peekInsert remove listItems apply val filter val transform numItems val mkTable find peek val find val peek val remov val list: val apply val

Polymorphic hash primitives from Caml Light

val hash
val hash_param : int -> int -> 'key -> int
val mkPolyTable : int * exn -> ("_key, '_data) hash_table

[('key, 'data) hash_table] is the type of hashtables with keys of type 'key and data values of type 'data.

82 [mkTable (hashVal, sameKey) (sz, exc)] returns a new hashtable, using hash function hashVal and equality predicate sameKey. The is a size hint, and exc is the exception raised by function find. It must be the case that sameKey(kl, k2) implies hashVal(kl) = hashVal(k2) for all kl,k2.

[numItems htbl] is the number of items in the hash table.

[insert htb] (k, d)] inserts data d for key k. If k already had an item associated with it, then the old item is overwritten.

ф. [find htb] k] returns d, where d is the data item associated with key k, or raises the exception (given at creation of htb]) if there is no such α

[peek htbl k] returns SOME d, where d is the data item associated with key k, or NONE if there is no such d.

[peekInsert htbl (k, d)] inserts data d for key k, if k is not already in the table, returning NOME. If k is already in the table, associated data value is d', then returns SOME d' and leaves the table unmodified.

[remove htb] k] returns d, where d is the data item associated with key k, removing d from the table; or raises the exception if there is no such d.

[listItems htb]] returns a list of the (key, data) pairs in the hashtable.

[apply f htbl] applies function f to all (key, data) pairs in hashtable, in some order. [map f htbl] returns a new hashtable, whose data items have been obtained by applying f to the (key, data) pairs in htbl. The new tables have the same keys, hash function, equality predicate, and exception, as htbl.

[filter p htb]] deletes from htbl all data items which do not satisfy predicate p.

104 POLYHASH

[transform f htbl] as map, but only the (old) data values are used when computing the new data values.

[copy htbl] returns a complete copy of htbl

[bucketSizes htbl] returns a list of the sizes of the buckets. This is to allow users to gauge the quality of their hashing function.

[hash k] returns the hash value of k, as a positive integer. If k1-k2 then hash(k1) = hash(k2), so this function can be used when creating hashtables. The application hash(k) always terminates, even on cyclic structures. (From the Caml Light implementation).

[hash_param n m k] computes a hash value for k with the same properties as for hash. The parameters n and m give more precise control over hashing. Hashing performs a depth-first, right-to-left traversal of the structure k, stopping after n meaningful nodes were encountered, or m nodes, meaningful or not, were encountered. Meaningful nodes are: integers, floating-point numbers, strings, characters, booleans, references, and constant constructors.

[mkPolyTable (sz, exc)] creates a new hashtable using the polymorphic hash function (hash) and ML equality (op =); the integer sz is a size hint and the exception exc is to be raised by find.

fromtag : dyntype -> string ftype : dbresult -> int -> dyntype ftypes : dbresult -> dyntype Vector.vector val val

val applyto : $(a \rightarrow (a \rightarrow b) \rightarrow b)$

query as an HTML table Formatting the result of a database

: dbconn -> string -> Msp.wseq formattable : dbresult -> Msp.wseq val showquery val

[dbconn] is the type of connections to a PostgreSQL database

[dbresult] is the type of result sets from SQL queries.

[oid] is the type of PostgreSQL internal object identifiers.

 \subseteq [openbase { dbhost, dbport, dboptions, dbtty, dbname, dbuser, dbpwd opens a connection to a PostgreSQL database server on the given the given constructed one) on the given port (default 5432), with the given options (default the empty string), with error logging on the given options (default), to the given mane (defaults to the user's login name), for the given user name (defaults to the user's login name), and the given password (default none). The result is a connection which may be used in subsequent queries.

No further [closebase dbconn] closes the database connection. queries can be executed

db dbconn] returns the name of the database.

acconn returns SOME h, where h is the database server host if the connection uses the Internet; returns NoNE if the [host dbconn] returns SOME h, where h is the database connection is to a socket on the local server. [options dbconn] returns the options given when opening the database.

[port dbconn] returns the port number of the connection

POSTGRES

[tty dbconn] returns the name of the tty used for logging.

[status dbconn] returns true if the connection is usable,

2 [reset dbconn] attempts to close and then reopen the connection the database server [errormessage dbconn] returns NONE if no error occurred, and SOME msg if an error occurred, where msg describes the error.

[execute dbconn query] sends an SQL query to the database server for execution, and returns a resultset dbres.

[resultstatus dbres] returns the status of the result set dbres. After a select query that succeeded, it will be Tuples_ok.

set intuples dbres] returns the number of tuples in the result after a query

[emdtuples dbres] returns the number of tuples affected by insert, update, or delete ${\rm SQL}$ command.

an

[nfields dbres] returns the number of fields in each tuple after

[fname dbres fno] returns the name of field number fno (in the The fields are numbered 0, result set after a query). [fnames dbres] returns a vector of the field names (in the result set after a query). [fnumber dbres fname] returns SOME i where i is the number (0, 1, ...) of the field called fname (in the result set after a query), if the result set contains such a field name; returns NOME otherwise.

[ftype dbres fno] returns the dyntype of field number fno (in the result set after a query) [ftypes dbres] returns a vector of the dyntypes (in the result set after a query). [fromtag dt] returns the name of the preferred PostgreSQL type used to represent values of the dyntype dt. This may be used when building 'create table' statements.

[getint dbres fno tupno] returns the integer value of field number fno in tuple tupno of result set dbres. Raises Null if the value is NUIL.

[getreal dbres fno tupno] returns the floating-point value of field number fno in tuple tupno of result set dbres. Raises Null if the value is NULL.

[getstring dbres fno tupno] returns the string value of field number fno in tuple tupno of result set dbres. Raises Null if the value is NULL.

[getdate dbres fno tupno] returns the date (yyyy, mth, day) value of field number fno in tuple tupno of result set dbres. Raises Null if the value is NULL. Raises Fail if the field cannot be scanned as a date.

[gettime dbres fno tupno] returns the time-of-day (hh, mm, ss) value of field number fno in tuple tupno of result set dbres. Raises Null if the value is NULL. Raises Fail if the field camnot be scanned as a time.

[getdatetime dbres fno tupno] returns the Date.date value of field number fno in tuple tupno of result set dbres. Raises Null if the value is NULL. Raises Fail if the field cannot be scanned as a

108

getbool dbres fno tupnol returns the boolean value of field number ino in tuple tupno of result set dbres. Raises Null if the value is NULL.

[ismull dbres fno tupno] returns true if the value of field number fno in tuple tupno of result set dbres is NULL; false otherwise.

[getdynfield dbres fno tupno] returns the value of field number fno in tuple tupno of result set dbres as a dynval (a wrapped value).

A NULL value is returned as NullVal. Note that the partial application (getdynfield dbres fno) precomputes the type of the field fno. Hence it is far more efficient to compute

Int val getfno = getdynfield dbres fno
in tabulate(ntuples dbres, getfno) end

than to compute

let fun getfno tupno = getdynfield dbres fno tupno in tabulate(ntuples dbres, getfno) end because the latter repeatedly computes the type of the field.

[getdyntup dbres tupno] returns the fields of tuple tupno in result set dbres as a vertor of Amount of district the fields of tuple tupno in result of the fields of tuple tupno in result.

[getdyntups dbres] returns all tuples of result set dbres as a vector of vectors of dynvals.

[dynval2s dv] returns a string representing the dynval dv.

[applyto x f] computes f(x). This is convenient for applying several functions (given in a list or vector) to the same value: map (applyto 5) (tabulate(3, getdynfield dbres))

[getdynfield dbres 0 5, getdynfield dbres 1 5, getdynfield dbres 2 5]

[copytableto(dbconn, tablename, put)] executes a "COPY TABLE TO" statement, applies the function put to every tuple of the table, represented as a line of text (not terminated by newline \n), and cleans up at the end. For instance, to copy the contents of a table t to a text stream s (one tuple on each line), define

fun put line =
 (TextIO.output(s, line); TextIO.output(s, "\n"))

and execute

copytableto(dbconn, "t", put).

[copytablefrom(dbconn, tablename, useput)] executes a "COPY TABLE FROM" statement, creates a put function for copying lines to the table, passes the put function to useput, and cleans up at the end. The put function may be called multiple times for each line character has as usual. For instance, to copy the contents of a text stream s to a table t, define

fun useput put =
while not (TextIO.endofStream s) do put(TextIO.inputLine s);

and execute

copytablefrom(dbconn, "t", useput). Note that TextIO.inputLine preserves the newline at the end of each

[formattable dbresult] returns a wseq representing an HTML table. The HTML table has a column for every field in the dbresult. The first row is a table header giving the names of the fields in the dbresult. The remaining rows correspond to the tuples in the dbresult, in the order they are provided by the database server. Null fields are shown as NULL.

[showquery dbconn query] sends the SQL query to the database server, then uses formattable to format the result of the query.

PROCESS

Module Process

-- SML Basis Library OS. Process

type status

: status : status success val val

: status -> bool val isSuccess

: string -> status val system : (unit -> unit) -> unit : status -> 'a

-> unit exit . scatus -> val atExit
val exit
val terminat
val sleep

: string -> string option getEnv val Portable functions for manipulating processes

[success] is the unique status value that signifies successful termination of a process. Note: MS DOS (sometimes) believes that all processes are successful.

[failure] is a status value that signifies an error during execution of a process. Note that in contrast to the success value, there may be several distinct failure values. Use function isSuccess to reliably test for success.

represents a [isSuccess sv] returns true if the status value sv repr. successful execution, false otherwise. It holds that isSuccess success = true and isSuccess failure = false. [system cmd] asks the operating system to execute command cmd, and returns a status value.

[atExit act] registers the action act to be executed when the current SML program calls Process.exit. Actions will be executed in reverse order of registration.

[exit i] executes all registered actions, then terminates the process with completion code

[terminate i] terminates the SML process with completion code i (but without executing the registered actions).

[sleep t] suspends this process for approximately the time indicated by t. The actual time slept depends on the capabilities of the underlying system and the system load. Does not sleep at all if $t \leftarrow r$ Time. zeroTime.

[getEnv evar] returns SOME s if the environment variable evar is defined and is associated with the string s; otherwise NONE.

110 RANDOM

Module Random

```
type generator

type generator
val newgenseed : real -> generator
val newgen : unit -> generator
val newgen : unit -> generator
val random : generator -> real
val randomlist : int * generator -> real list
val range : int * int -> generator -> int
val rangelist : int * int -> jenerator -> int
val rangelist : int * int -> jenerator -> int list
```

```
[generator] is the type of random number generators, here the linear congruential generators from Paulson 1991, 1996.

[newgenseed seed] returns a random number generator with the given seed.

[newgen ()] returns a random number generator, taking the seed from the system clock.

[random gen] returns a random number in the interval [0..1).

[randomlist (n, gen)] returns a list of n random numbers in the interval [0,1).

[range (min, max) gen] returns an integral random number in the range [min, max). Raises Fail if min > max.

[rangelist (min, max) (in, gen)] returns a list of n integral random numbers in the range [min, max). Raises Fail if min > max.
```

RBSET

Module Rbset

Rbset -- ordered sets implemented by red-black trees Intention: should resemble SML/NJs ORD_SET signature

exception NotFound exception NonMonotonic

signature Rbset = sig

type 'item set

```
item set * 
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               -> 'item set -> 'newitem set : ('item -> 'newitem -> order)

```

['item set] is the type of sets of ordered elements of type 'item. The ordering relation on the elements is used in the representation of the set. The result of combining or comparing two sets with different underlying ordering relations is undefined. The implementation uses Okasaki-style red-black trees.

end

[empty ordr] creates a new empty set with the given ordering relation.

[singleton ordr i] oreates the singleton set containing i, with the given ordering relation.

[add(s, i)] adds item i to set s.

[addList(s, xs)] adds all items from the list xs to the set s.

RBSET 112

[isEmpty s] returns true if and only if the set is empty.

[equal(s1, s2)] returns true if and only if the two sets have the same elements, as determined by the ordering relation given when the sets were created. s2. [isSubset(s1, s2)] returns true if and only if s1 is a subset of

[member(s, i)] returns true if and only if i is in s.

[delete(s, i)] removes item i from s. Raises NotFound if i is not in

[numItems s] returns the number of items in set s.

[union(s1, s2)] returns the union of s1 and s2.

[intersection(s1, s2)] returns the intersection of s1 and s2.

(difference(s1, s2)] returns the difference between s1 and s2 (that is, the set of elements in s1 but not in s2).

[listItems s] returns a list of the items in set s, in increasing

[app f s] applies function f to the elements of s, in increasing order.

[revapp f s] applies function f to the elements of s, in decreasing

[fold] f $\,$ e $\,$ s] applies the folding function f to the entries of the set in increasing order.

[foldr f e s] applies the folding function f to the entries of the set in decreasing order.

[map (f, ordr) s] creates a new set with underlying ordering ordr by applying function f to all elements of the set s.

[mapMono (f, ordr) s] creates a new set by applying the strictly monotonically increasing function f to all elements of s. The new set will have ordering ordr. This is faster than map (f, ordr) s by a logarithmic factor, but the function must satisfy ordr(f, x, f y) = ordr'(x, y) to ordr'(x) the ordering relation on s; otherwise exception NonMonotonic is thrown.

[find p s] returns SOME i, where i is an item in s which satisfies p, if one exists; otherwise returns NONE. Traverses the entries of the set in increasing order.

[min s] returns SOWE i, where i is the least item in the set s, if s is non-empty; returns NONE if s is empty.

[max s] returns SOME i, where i is the greatest item in the set s, if s is non-empty; returns NONE if s is empty.

[hashCode h s] returns the hashcode of the set, which is the sum of the hashcodes of its elements, as computed by the function h.

[compare (s1, s2)] returns LESS, EQUAL or GREATER according as s1 precedes, equals or follows s2 in the lexicographic ordering that would be obtained by comparing the sorted lists of elements of the two sets. It holds that equal(s1, s2) if and only if compare(s1, s2) = LESS isSubset(s1, s2) implies compare(s1, s2) = LESS isSubset(s2, s1) implies compare(s1, s2) = GREATER

[subset(s, intv)] returns a set of those elements of s that belong to the interval intv. The intervals have the following meaning:

RBSET

	<> GREATER	= LESS	<> GREATER	and $cmp(e, e2) = LESS$
	e)	e2)	e)	e2)
	cmp(el,	cmp(e,	cmp(el,	cmp(e,
				and
all elements	for	for	for	
	Φ	Φ	Φ	
	elements	elements e for	elements	
denotes	denotes	denotes	denotes	
			e2)	
All	From el	To e2	FromTo(e1,	

[sublist(s, intv)] returns a list, in order, of those elements of s that belong to the interval intv. Thus sublist(s, All) is equivalent to listItems s.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 [toDefault x] is x.
777<sub>7</sub>7
```

[floor r] is the largest integer <= r (rounds towards minus infinity). May raise Overflow.

[ceil r] is the smallest integer >= r (rounds towards plus infinity). May raise Overflow.

[trunc r] is the numerically largest integer between r and zero (rounds towards zero). May raise Overflow.

[round r] is the integer nearest to r, using the default rounding mode. May raise Overflow.

 $[=(x,\ y)]$ is equivalent to x=y in Moscow ML (because of the absence of NaNs and Infs).

 $[!=(x,\ y)]$ is equivalent to x<>y in Moscow ML (because of the absence of NaNs and Infs).

 $[?=(\kappa,\ y)]$ is false in Moscow ML (because of the absence of NaNs and Infs).

[fmt spec r] returns a string representing r, in the format specified by spec (see below). The requested number of digits must be >= 0 in the SCI and FIX formats and > 0 in the GEN format; otherwise Size is raised, even in a partial application fmt(spec).

C printf	B. B. A. A. A. A.
	scientific, oscientific, n fixed-point, 6 fixed-point, n auto choice, 12 auto choice, n
spec	SCI NONE SCI (SOME n) FIX NONE FIX (SOME n) GEN NONE

[toString r] returns a string representing r, with automatic choice of format according to the magnitude of r. Equivalent to (fmt (GEN NONE) r).

[fromString s] returns SOME(r) if a floating-point numeral can be scanned from a prefix of string s, ignoring any initial whitespace; returns NOME otherwise. The valid forms of floating-point numerals are described by: [+~-]?([[0-9]+(\.[0-9]+)?) | (\.[0-9]+))([eE][+~-]?([0-9]+)?

[scan getc charszc] attempts to scan a floating-point number from the character source charsrc, using the accessor getc, and ignoring any initial whitespace. If successful, it returns SOWE(r, rest) where r is the number scanned, and rest is the unused part of the character source. The valid forms of floating-point numerals are described by: [+-1?([0-9]+(\.[0-9]+(\.[0-9]+)?)|(\.[0-9]+))([eE][+-]?[0-9]+)?

[('key, 'a) dict] is the type of applicative maps from domain type 'key to range type 'a, or equivalently, applicative dictionaries with keys of type 'key and values of type 'a. They are implemented as Okasaki style red-black trees.

[mkDict ordr] returns a new, empty map whose keys have ordering

[insert(m, i, v)] extends (or modifies) map m to map i to v.

[find (m, k)] returns v if m maps k to v; otherwise raises NotFound

[peek(m, k)] returns SOME v if m maps k to v; otherwise returns NONE.

[remove(\mathfrak{m} , k)] removes k from the domain of \mathfrak{m} and returns the modified map and the element v corresponding to k. Raises NotFound if k is not in the domain of \mathfrak{m} .

[numItems m] returns the number of entries in m (that is, the size domain of m). [listItems m] returns a list of the entries $(k,\ v)$ of keys k and the corresponding values v in m, in order of increasing key values.

[app f m] applies function f to the entries (k, v) in m, in increasing order of k (according to the ordering ordr used create the map or dictionary).

[revapp f m] applies function f to the entries $(k,\ v)$ in decreasing order of k.

[fold] f e m] applies the folding function f to the entries $(k\,,\,$ in m, in increasing order of $k\,.$

ò

[foldr f e m] applies the folding function f to the entries $(k\,,\,$ in m, in decreasing order of k.

[map f m] returns a new map whose entries have form $(k,\;f(k,v)),$ where $(k,\;v)$ is an entry in m.

[transform f m] returns a new map whose entries have form $(k,\ f\ v),$ where $(k,\ v)$ is an entry in m.

```

['item set] is the type of sets of ordered elements of type 'item. The ordering relation on the elements is used in the representation of the set. The result of combining two sets with different underlying ordering relations is undefined. The implementation uses Okasaki-style Red-Black trees.

[empty ordr] creates a new empty set with the given ordering

[singleton ordr i] creates the singleton set containing i, with the given ordering relation.

[add(s, i)] adds item i to set s.

[addList(s, xs)] adds all items from the list xs to the set s.

[retrieve(s, i)] returns i if it is in s; raises NotFound otherwise.

[peek(s, i)] returns SOME i if i is in s; returns NONE otherwise.

[isEmpty s] returns true if and only if the set is empty.

[equal(s1, s2)] returns true if and only if the two sets have the same elements.

a subset of [isSubset(s1, s2)] returns true if and only if s1 is

[member(s, i)] returns true if and only if i is in s.

[delete(s, i)] removes item i from s. Raises NotFound if i is not in s. [numItems s] returns the number of items in set

[union(s1, s2)] returns the union of s1 and s2.

[intersection(s1, s2)] returns the intersection of s1 and s2.

[difference(s1, s2)] returns the difference between s1 and s2 (that

118 REDBLACK

is, the set of elements in s1 but not in s2).

[listItems s] returns a list of the items in set s, in increasing order

[app f s] applies function f to the elements of s, in increasing order.

[revapp f s] applies function f to the elements of s, in decreasing order.

[fold] f e s] applies the folding function f to the entries of the set in increasing order.

[foldr f e s] applies the folding function f to the entries of the set in decreasing order.

[find p s] returns SOME i, where i is an item in s which satisfies p, if one exists; otherwise returns NOME. Traverses the entries of the set in increasing order.

val app
val fold
```

This structure provides pattern matching with POSIX 1003.2 regular

expressions.

The form and meaning of Extended and Basic regular expressions are described below. Here R and S denote regular expressions; m and n denote natural numbers; L denotes a character list; and d denotes a decimal digit:

	times times 'string mes
	Match the character c Match any character Match R zero or more times Match R or S Match R or S Match R or the empty string Match R exactly m times Match R at least m times
Meaning	Match the Match Ratch Ra
Basic	C R* R*+ R* S R* S R* ? R* ? R* ? R*
Extended	C C C C C C C C C C C C C C C C C C C

120

```
R{m,n} R\{m,n\} Match R at least m and at most n times [L] Match any character in L [^L] Match any character not in L Match at string's beginning $ $ Match at string's beginning Match at string's end Match R as a group; save the match A Match R as may as a group d Match L asme as previous group d Match + -- similarly for *.[^s]* Match + -- similarly for *.[^s]* Match + -- similarly for *.[^s]* Match + -- similarly for | ?[^s]* ()
```

Some example character lists L:

```
Match punctuation character Match SNL #", #"\t", #"\t", #"\t", #"\t", #"\t" Match SNL #" Match etter Match hexadecimal digit; same as [0-9a-fA-P]
                                                                                                                                                                                                                                                                                                              Match lowercase Danish letters (ISO Latin 1)
                                  Match non-digit
Match - or + or * or / or *
Match lowercase letter or hyphen (-)
Match hexadecimal digit
Match letter or digit
                                                                                                                                             Match ASCII control character
Match decimal digit; same as [0-9]
Same as [:print:] but not [:space:]
                     or
       or
Match vowel: a or e or i or o or
Match digit: 0 or 1 or 2 or ...
                                                                                                                                                                                                    Match lowercase letter
Match printable character
                                                                                                                                Match letter
                                                                                                                                                                                                                                                                                                                [[:lower:]æøå]

                                                                                                                                                 [:cntrl:]]
[:digit:]]
                                                                                                                                                                                  graph:
                                                                                                                                                                                                      [:lower:]
[:print:]
                                                                                                                                :alpha:
                                                                                                                                                                                                                                          punct:
```

Remember that backslash $(\)$ must be escaped as "\\" in SML strings.

[regcomp pat cflags] returns a compiled representation of the regular expression pat. Raises Regex in case of failure.

[cflag] is the type of compilation flags with the following meanings:

[Extended] : compile as POSIX extended regular expression.
[Icase] : compile case-insensitive march.
[Newline] : make the newline character \n significant, so ^ matches just after newline (\n), and \$ matches just before \n.

Example: Match SML integer constant:
regcomp "^~?[0-9]+\$" [Extended]

Example: Match SML alphanumeric identifier: regcomp "^[a-zA-Z0-9][a-zA-Z0-9'_]*\$" [Extended]

Example: Match SML floating-point constant: regroup " $^{-1}$ [0-9]+(\\.[0-9]+(\\.[0-9]+(\\.[0-9]+\]){" [Extended]

Example: Match any HTML start tag; make the tag's name into a group: regcomp "<([[:alnum:]]+)[^>]*>" [Extended] [regexec regex eflags s] returns SOME(vec) if some substring of s matches regex, NONE otherwise. In case of success, vec is the match vector, a vector of substrings such that vec[0] is the (longest leftmost) substring of s matching regex, and vec[1], vec[2], ... are substrings matching the parenthesized groups in pat (numbered 1, 2, ... from left to right in the order of their opening parentheses). For a group that does not take part in the match, such as (ab) in "(ab) [(ad)" when matched against the string "xcdy", the corresponding substring is the empty substring at the beginning of the underlying string. For a group that takes part in the match repeatedly, such as the group (b+) in "(a(b+))*" when matched against "babbabb", the corresponding substring is the last (rightmost) one matched.

[eflag] is the type of end flags with the following meaning:

[Notbol] : do not match ^ at beginning of string.

[Noteol] : do not match \$ at end of string.

REGEX

[regexecBool regex eflags s] returns true if some substring of s matches regex, false otherwise. Equivalent to, but faster than, Obtion.isSome(regexec regexe eflags s).

option..issoume(legeact regrated triags s).

[regnexec regex eflags sus] returns SOME(vec) if some substring of sus matches regex, NOME otherwise. The substrings returned in the vector vec will have the same base string as sus. Useful e.g. for splitting a string into fragments separated by substrings matching some regular expression.

[regnexecBool regex eflags sus] returns true if some substring of sus matches regex, false otherwise. Equivalent to, but faster than, Option.isSome(regnexec regexec eflags sus).

[regmatchBool { pat, tgt } cflags eflags] is equivalent to regexecBool (regcomp pat cflags) eflags tgt but more efficient when the compiled regex is used only once.

[replace regex repl s] finds the (disjoint) substrings of s matching regex from left to right, and returns the string obtained from s by applying the replacer list repl to every such substring (see below). Raises Regex if it fails to make progress in decomposings, that is, if regex matches an empty string at the head of s or immediately after a previous regex match. Example use: delete all HTML tags from s:

replace (regcomp "<[^>]+>" [Extended]) [] s

[replace] regex repl s] finds the leftmost substring bl of s matching regex, and returns the string resulting from s by applying the replacer list repl to the match vector vecl (see below).

Let x0 be a substring matching the entire regex and xi be the substring matching the 1'th parenthesized group in regex; thus xi evec[i] where vec is the match vector (see regexec above). Then a single replacer evaluates to a string as follows:

```
[Str s] gives the string s
[Sus i] gives the string xi
[Tr (f, i)] gives the string [(xi)
[Trs f] gives the string f(vec)
```

A replacer list repl evaluates to the concatenation of the results of the replacers. The replacers are applied from left to right.

[substitute regex f s] finds the (disjoint) substrings bl, ..., bn of s matching regex from left to right, and returns the string obtained from s by replacing every bi by f(bi). Function f is applied to the matching substrings from left to right. Raises Regex if it fails to make progress in decomposing s. Equivalent to replace regex [Tr (f, 0)] s

[substitute1 regex, and returns the leftmost substring b of s matching regex, and returns the string obtained from s by replacing that substring by f(b). Equivalent to replace1 regex [Tr (f, 0)] s

[map regex f s] finds the (disjoint) substrings of s matching regex from left to right, applies f to the match vectors vecl, ..., vecn, and returns the list [f(vecl), ..., f(vecn)]. Raises Regex if it falls to make progress in decomposing s.

[app regex f s] finds the (disjoint) substrings of s matching regex from left to right, and applies f to the match vectors vecl, vecn. Raises Regex if the regex fails to make progress in decomposing s.

122 REGEX

```
[fields regex s] returns the list of fields in s, from left to cright. A field is a (possibly empty) maximal substring of snot containing any delimiter. A delimiter is a maximal substring of snot matches regex. The eflags Notbol and Noteol are set. Raises Regex if it fails to make progress in decomposing s.

Example use:

[tokens regex s] returns the list of tokens in s, from left to containing any delimiter. A delimiter is a maximal substring of snot containing any delimiter. A delimiter. A delimiter is a maximal substring that matches regex. The eflags Notbol and Noteol are set. Raises Regex if it fails to make progress in decomposing s. Equivalent to List.filter (not o Substring.) simply) (fields regex s)

Two tokens may be separated by more than one delimiter, whereas two fields are separated by weately one delimiter. If the only delimiter is the character #"|", then

"abc| |def" contains three fields: "abc" and "adf"
"abc| |def" contains three fields: "abc" and "def"
"abc| |def" contains three fields: "abc" and "def"
"abc| |def" contains three fields: "abc" and "def"

by of s matching regex from left to right, and splits s into the substrings

a) bl. al, b2, a2, ..., bn, an where n >= 0 and where a0 is the (possibly empty) substring of s preceding the first match, and ai is the (possibly empty) substring between the matches bi and b(1+1). Then it computes and returns where veci is the match vector corresponding to bi. Raises Regex if it fails to make progress in decomposing s.

If we define the match set in a fail is a fail is a fail it fails to make progress in decomposing s.

If we define the auxiliary functions fun few for a substring. Substring.

val toWord : signal -> Word.word val fromWord : Word.word -> signal

[signal] is the type of ${\tt Unix/Posix-style}$ signals, which can be sent to another process.

[toWord sig] returns the signal number as an unsigned word.

[fromWord w] returns the signal whose number is w.

[abrt] is SIGABRT, the abort signal from abort(3).

[alrm] is SIGALRM, a timer signal from alarm(1).

[bus] is SIGBUS, a bus error

is SIGFPE, a floating point exception. [be]

[hup] is SIGHUP, a hangup.

[ill] is SIGILL, an illegal instruction.

[int] is SIGINT, an interrupt.

[kill] is SIGKILL, the kill signal.

[pipe] is SIGPIPE, a broken pipe.

[quit] is SIGQUIT, a quit from keyboard.

[segv] is SIGSEGV, a segmentation violation.

[term] is SIGTERM, the termination signal.

[usr1] is SIGUSR1, the first user signal.

[usr2] is SIGUSR2, the second user signal.

[chld] is SIGCHLD, child process stopped or terminated.

[cont] is SIGCONT, continue if stopped.

[stop] is SIGSTOP, signal to stop process.

SIGNAL

```
[ttou] is SIGTTOU, tty output for background process.
                                                                 [ttin] is SIGTTIN, tty input for background process.
[tstp] is SIGTSTP, a stop signal typed at the tty.
```

126 SOCKET

Module Socket

Returns (sock, addrs) where sock is a copy of the socket sock, bound to that connection, and addr is the address of the communications counterpart (the other end of the connection). Blocks if no connections are pending. The stream socket sock must have been assigned a name (with bind) and must be listening for connections (following a call to listen).
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           [('addressfam, 'socktype) sock] is the type of sockets with address
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              Structure Socket defines functions for creating and using sockets, a means for communication between SML processes on the same machine
                                                                                                                                                                                                                                                                                                                                                                                                            fileDgram ()] returns a new datagram socket for the Unix protocol
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              [fileStream ()] returns a new stream socket for the Unix protocol
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 [inethddr inetaddr portno] returns a socket address for the Internet protocol family, created from the given Internet number (e.g. "130.225.40.253") and port number (e.g. 8080).
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      [bind sock addr] binds the socket sock to the address addr, that is, assigns the name addr to the socket. Binding a name in the
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         [filehaddr fname] returns a socket address for the Unix protocol family, created from the given file name fname.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       inetDgram ()] returns a new datagram socket for the Internet
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  inetStream ()] returns a new stream socket for the Internet
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  active, or connected, stream sockets
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               ['addressfam sock_addr] is the type of sockets addresses.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    The Unix address family (file)

```

SOCKET 128

must Unix protocol family creates a socket in the file system that be deleted when it is no longer needed [connect (sock, addr)] attempts to connect socket sock to the communications peer at address addr. If sock is a datagram socket, then addr is the address to which datagrams is to be sent, and the only address from which datagrams will be accepted. If sock is a stream socket, then addr specifies another socket to which to

[listen (sock, queuelen)] enables the passive stream socket sock to accept incoming connections. The parameter queuelen specifies the maximal number of pending connections. Further connections from clients may be refused when this limit is reached.

close sock] closes the socket.

[shutdown sock shutdown_mode] shuts down socket sock for fucommunication, as specified by the shutdown_mode parameter:

no further receives are allowed; NO_RECVS]

no further receives or sends are allowed NO_RECVS_OR_SENDS]

no further sends are allowed;

NO_SENDS]

getinetaddr addr] returns the Internet number (e.g. "130.225.40.253") of the Internet socket address addr.

if size = SOME s it represents buf[ofs..ofs+s-l];
if size = NOME it represents buf[ofs..len-l] where len is buf's length
When the subbuffer is used in a call, exception Subscript will be raised
if ofs < 0 or size < 0 or ofs+size > len. buf] is the type of records { buf, ofs, size } which represent subvectors or subarrays:

on Returns the number of bytes sent. [sendVec (sock, vecbuf)] transmits the bytes from buffer vecbuf Blocks until sufficient space is available at the socket. active stream socket sock.

[sendArr (sock, arrbuf)] is analogous til sendVec.

buffer vecbuf on the active stream socket sock, observing the out_flags. Returns the number of bytes sent. Blocks until sufficient space is available at the socket. [sendVec' (sock, vecbuf, out_flags)] transmits the bytes from

[out_flags] is the type of records { don't_route, oob } in which the field don't_route specifies whether routing should be bypassed, and the field oob specifies whether data should be sent out-of-band.

sendArr' (sock, arrbuf, out_flags)] is analogous til sendVec'

13 [sendyecTo (sock, addr, vecbuf)] transmits the bytes from buffer vecbuf on the datagram socket sock to the target address addr. Returns the number of bytes sent. Blocks until sufficient space available at the socket.

sendArrTo (sock, addr, arrbuf)] is analogous til sendVecTo.

[sendVecTo' (sock, addr, vecbuf, out_flags)] transmits the bytes from buffer vecbuf on the datagram socket sock to the target address addr. observing the out_flags. Returns the number of bytes sent. Block until sufficient space is available at the socket. See above for a description of vecbuf and out_flags.

sendArrTo' (sock, addr, arrbuf, out_flags)] is analogous til sendVecTo'

[recvVec (sock, n)] receives up to n bytes from the active stream socket seturns a byte vector containing the bytes actually received. Books until some data become available at the socket, then returns any available data, up to n bytes. Excess data are

not lost; they are available for subsequent receive calls

SOCKET

eived. Blocks Excess data are socket sock into the subarray arrbuf, up to the available space. If #size(arrbuf) = SOME(s) the available space is s bytes; if #size(arrbuf) = NOME the available space is len - #ofe(arrbuf) bytes. Returns the number of bytes actually received. Blocks until some data become available at the socket. Excess data are not lost; they are available for subsequent receive calls. [recvArr (sock, arrbuf)] receives bytes from the active stream

[recvVec' (sock, n, in_flags)] receives up to n bytes from the active stream socket sock, observing the in_flags. Returns a byte vector containing the bytes actually received. Blocks until some data become available at the socket, then returns any available data, up to n bytes. Data in excess of n bytes are not lost; they are available for subsequent receive calls.

field the [in_flags] is the type of records { peek, oob } in which the peek specifies that the data read should not be removed from receive queue, and the field oob specifies that data may be received out-of-band.

stream socket sock into the subarray arrbuf, observing the in_flags, up to the available space. Returns the number of bytes actually received. Blocks until some data become available at the [recvArr' (sock, arrbuf, in_flags)] receives bytes from the active socket. Excess data are not lost; they are available for subsequent receive calls.

[recvVecFrom (sock, n)] receives up to n bytes from the datagram socket sock. Returns a byte vector containing the bytes actually received. Blocks until some data become available at the socket, then returns any available data, up to n bytes. [recvArrFrom (sock, arrbuf)] receives bytes from the datagram socket sock into the subarray arrbuf. Returns the number of bytes actually received. Blocks until some data become available at the

[recovecFrom' (sock, n, in_flags)] receives up to n bytes from the datagram socket sock, observing the in_flags (see above). Returns (vec, addr) where vec is a byte vector containing the bytes actually received, and addr is the source address of the message. Blocks until some data become available at the socket, then returns any available data, up to n bytes.

[recvArrFrom' (sock, arrbuf, in_flags)] receives bytes from the datagram socket sock into the array buffer arrbuf, observing the in_flags (see above). Returns (n. addr) where n is the number of bytes actually received, and addr is the source address of the Blocks until some data become available at the socket. message.

[sockDesc sock] returns a descriptor for the socket sock, to be used in a call to select.

returns GREATER is sdl precedes sd2, and returns EQUAL otherwise. precedes sd2 [compare (sdl, sd2)] compares sdl and sd2 according to an unspecified total ordering, and returns LESS if sdl preced

[sameDesc (sd1, sd2)] returns true if sd1 and sd2 describe the same socket. Equivalent to compare(sd1, sd2) = EQUAL [select { rds, wrs, exs, timeout }] blocks the calling process until some input/output operations become possible on some sockets. The call will check the sockets described in rds for reading, those in wrs for exceptional conditions. Heturns { rds, wrs, exs } where rds now is a list of describtors of sockets ready for reading, wrs are ready for writing, and exs have exceptional conditions. The order of the socket describtors in the results is the same as their order in the corresponding arguments. If timeout is NOME then the call blocks until some input/output operations become possible; if timeout is SOME(t) then the call

130 SOCKET

blocks for at most time t.

A server socket is considered ready for reading if there is a pending connection which can be accepted with 'accept'. A client socket is ready for writing when its connection is fully established.

[('key, 'a) dict] is the type of applicative maps from domain type 'key to range type 'a, or equivalently, applicative dictionaries with keys of type 'key and values of type 'a. They are implemented as ordered splay-trees (Sleator and Tarjan).

[mkDict ordr] returns a new, empty map whose keys have ordering ordr.

[insert(m, i, v)] extends (or modifies) map m to map i to v.

[find (m, k)] returns v if m maps k to v; otherwise raises NotFound.

[peek(m, k)] returns SOME v if m maps k to v; otherwise returns NONE.

[remove(m, k)] removes k from the domain of m and returns the modified map and the element v corresponding to k. Raises NotFound if k is not in the domain of m.

[numItems m] returns the number of entries in m (that is, the size of the domain of m).

[listItems m] returns a list of the entries $(k,\;v)$ of keys k and the corresponding values v in m, in increasing order of k.

[app f m] applies function f to the entries (k, v) in m, in increasing order of k (according to the ordering ordr used to create the map or dictionary).

[revapp f m] applies function f to the entries $(k,\;\nu)$ in m, in decreasing order of k.

[fold] f e m] applies the folding function f to the entries $(k,\ v)$ in m, in increasing order of k.

[foldr f e m] applies the folding function f to the entries $(k,\ v)$ in m, in decreasing order of k.

[map f m] returns a new map whose entries have form (k, f(k,v)), where (k, v) is an entry in m.

[transform f m] returns a new map whose entries have form $(k,\ f\ v)$, where $(k,\ v)$ is an entry in m.

['item set] is the type of sets of ordered elements of type 'item. The ordering relation on the elements is used in the representation of the set. The result of combining two sets with different underlying ordering relations is undefined. The implementation uses splay-trees (Sleator and Tarjan).

[empty ordr] creates a new empty set with the given ordering relation.

[singleton ordr i] creates the singleton set containing i, with the given ordering relation.

[add(s, i)] adds item i to set s.

[addList(s, xs)] adds all items from the list xs to the set s.

[retrieve(s, i)] returns i if it is in s; raises NotFound otherwise

[peek(s, i)] returns SOME i if i is in s; returns NONE otherwise.

[isEmpty s] returns true if and only if the set is empty.

[equal(s1, s2)] returns true if and only if the two sets have the same elements.

[isSubset(s1, s2)] returns true if and only if s1 is a subset of s2 [member(s, i)] returns true if and only if i is in s. [delete(s, i)] removes item i from s. Raises NotFound if i is not in s.

[numItems s] returns the number of items in set s.

[union(s1, s2)] returns the union of s1 and s2.

(intersection(s1, s2)) returns the intersectionof s1 and s2.

[difference(s1, s2)] returns the difference between s1 and s2 (that is, the set of elements in s1 but not in s2).

SPLAYSET

set s, in increasing [listItems s] returns a list of the items in order. in increasing ß Jo [app f s] applies function f to the elements

of the [fold] f e s] applies the folding function f to the entries in σĘ [revapp f s] applies function f to the elements

decreasing

set in increasing order.

[foldr f e s] applies the folding function f to the entries of the set in decreasing order. [find $p\ s$] returns SOWB i, where i is an item in s which satisfies p, if one exists; otherwise returns NONE.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                [concatWith sep ss] is the concatenation of all the strings in ss, using sep as a separator. Thus concatWith sep ss is the empty string "" concatWith sep [s] is s
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       [substring(s, i, n)] is the string s[i..i+n-1]. Raises Subscript if i<0 or n<0 or i+n>size s. Equivalent to extract(s, i, SOME n).
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  [concat ss] is the concatenation of all the strings in ss. Raises Size if the sum of their sizes is greater than maxSize.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               [string] is the type of immutable strings of characters, with constant-time indexing.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       [sub(s, i)] is the i'th character of s, counting from zero. Raises Subscript if i<0 or i>=size s.
                                                                                                                                                                                                                                                                                                                                                                                              : (char -> char) -> string -> string
: (char -> string) -> string -> string
: (char -> bool) -> string -> string list
: (char -> bool) -> string -> string list
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    [maxSize] is the maximal number of characters in a string.
                                                                                                                             : int

STRING

```
concatWith sep [s1, ..., sn] is concat[s1, sep, ..., sep, sn] Raises Size if the resulting string would have more than maxSize
```

[str c] is the string of size one which contains the character c.

[implode cs] is the string containing the characters in the list cs. Equivalent to concat (List.map str cs).

[explode s] is the list of characters in the string s.

[map f s] applies f to every character of s, from left to right, and returns the string consisting of the resulting characters. Equivalent to CharVector.map f s and to implode (List.map f (explode s)).

[translate f s] applies f to every character of s, from left to right, and returns the concatenation of the resulting strings. Raises Size if the sum of their sizes is greater than maxSize. Equivalent to concat (List.map f (explode s)).

[tokens p s] returns the list of tokens in s, from left to right, where a token is a non-empty maximal substring of s not containing any delimiter, and a delimiter is a character satisfying p.

[fields p s] returns the list of fields in s, from left to right, where a field is a (possibly empty) maximal substring of s not containing any delimiter, and a delimiter is a character satisfying p.

Two tokens may be separated by more than one delimiter, whereas two fields are separated by exactly one delimiter. If the only delimiter is the character #"|", then "abc| def" contains two tokens: "abc" and "def" abc | def" contains three fields: "abc" and "def"

[isprefix s1 s2] is true if s1 is a prefix of s2. That is, if there exists a string u such that s1 $^{\circ}$ u = s2.

[isSuffix s1 s2] is true if s1 is a suffix of s2. That is, if there exists a string t such that t $^{\wedge}$ s1 = s2.

[fromString s] scans the string s as an ML source program string, converting escape sequences into the appropriate characters. Does not skip leading whitespace. [isSubstring s1 s2] is true if s1 is a substring of s2. That is, if there exist strings t and u such that t ^ s1 ^ u = s2.

[toString s] returns a string corresponding to s, with non-printable characters replaced by ML escape sequences. Equivalent to String.translate Char.toString.

[fromCString s] scans the string s as a C source program string, converting escape sequences into the appropriate characters. Does not skip leading whitespace.

[toCString s] returns a string corresponding to s, with non-printable characters replaced by C escape sequences. Equivalent to String.translate Char.toCString.

Returns LESS, mal to, or [compare (s1, s2)] does lexicographic comparison, using the standard ordering Char.compare on the characters. Returns I EQUAL, or GREATER, according as s1 is less than, equal to, c greater than s2. [collate cmp (s1, s2)] performs lexicographic comparison, using the given ordering cmp on characters.

 $\mathbb{Z}^{\mathbb{Z}}$

136 STRING

 $\lceil > = \rceil$ compare strings lexicographically, using the representation ordering on characters.

STRINGCVT

Module StringCvt

This structure presents tools for scanning strings and values from functional character streams, and for simple formatthing.

[('elm, 'src) reader] is the type of source readers for reading a sequence of 'elm values from a source of type 'src. For instance, a character source reader

getc: (char, os) reader
is used for obtaining characters from a functional character source src of type cs, one at a time. It should hold that

getc src = SOME(c, src') if the next character in src getc src = SOME(c, src') if src contains no characters

A character source scanner takes a character source reader getc as argument and uses it to scan a data value from the character source and applies the scanner 'scan' to that source.

[scanString scan s] turns the string s into a character source and applies the scanner 'scan' to that source.

[split! p getc src] returns (pref, sulf) where pref is the longest prefix (left substring) of src all of whose characters shared to satisfy by and sulf is the remainder of src. That is, the first shared to satisfy the string string is the longest prefix (left substring) of src all of whose characters shared to satisfy the string string is the longest prefix (left substring) of src all of whose characters shared to satisfy the string string is the longest prefix (left substring) of src all of whose characters shared to satisfy the string strin

[split] p getc src] returns (pref, suff) where pref is the longest prefix (left substring) of src all of whose characters satisfy p, and suff is the remainder of src. That is, the first character retrievable from suff, if any, is the leftmost character not satisfying p. Does not skip leading whitespace.

[takel p getc src] returns the longest prefix (left substring) of src all of whose characters satisfy predicate p. That is, if the left-most character does not satisfy by, the result is the empty string. Does not skip leading whitespace. It holds that takel p getc src = #1 (split1 p getc src)

[dropl p getc src] drops the longest prefix (left substring) of src all of whose characters satisfy predicate p. If all characters do, it returns the empty source. It holds that dropl p getc src = #2 (split1 p getc src)

[skipWS getc src] drops any leading whitespace from src. Equivalent to drop1 Char.isSpace.

[padLeft c n s] returns the string s if size s >= n, otherwise pads s with (n - size s) copies of the character c on the left. In other words, right-justifies s in a field n characters wide.

STRINGCVT 138

[padRight c n s] returns the string s if size s >= n, otherwise pads s with (n - size s) copies of the character c on the right. In other words, left-justifies s in a field n characters wide.

SUBSTRING

Module Substring

Substring -- SML Basis Library

type substring

```
substring -> char substring) option
substring -> char option

substring -> char list
(char * char -> order) -> substring * substring -> order
(char * char -> order) -> substring -> order
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           [substring] is the type of substrings of a basestring, an efficient representation of a piece of a string. A substring (s,i,n) is valid if 0 \leftarrow i \leftarrow i+n \leftarrow size s, a substring (s,i,n) is valid in 0 \leftarrow i \rightarrow i+n \leftarrow size s. A valid substring (s,i,n) represents the string s(i,n) \leftarrow 1. Invariant in the implementation: Any value of type substring is valid.
                                                                                                                                                                                                                                                                                                                                                                                                        : (char -> bool) -> substring -> substring
: (char -> bool) -> substring -> substring * substring
: (char -> bool) -> substring -> substring * substring
: substring * int -> substring * substring
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          : (char -> bool) -> substring -> substring list

```

A substring is the same as a CharVectorSlice.slice, so substrings may be processed using the functions declared in CharVectorSlice.

[substring(s, i, n)] creates the substring (s, i, n), consisting of the substring of s with length n starting at i. Raises Subscript if i<0 or n<0 or i+n > size s. Equivalent to extract(s, i, SOME n).

[extract(s, i, NONE)] creates the substring (s, i, size s-i) consisting of the tail of s starting at i.
Raises Subscript if i<0 or i > size s.

'n, [extract(s, i, SOME n)] creates the substring (s, i,

SUBSTRING 94

÷ consisting of the substring of s with length n starting at Raises Subscript if i<0 or n<0 or i+n > size s.

[full s] is the substring (s, 0, size s).

[all s] is the same as full(s). Its use is deprecated.

[string sus] is the string s[i..i+n-1] represented by sus = (s, i, n).

sus = (s, i, n). [base sus] is the concrete triple (s, i, n), where [isEmpty (s, i, n)] true if the substring is empty (that is, n = 0) [getc sus] returns SOME(c, rst) where c is the first character and rst the remainder of sus, if sus is non-empty; otherwise returns

Note that

#1 o valOf o scanFn Substring.getc is equivalent to, but more efficient than, valOf o StringCvt.scanString scanFn o Substring.string

[first sus] returns SOME c where c is the first character in sus, if sus is non-empty; otherwise returns NONE.

[triml k sus] returns sus less its leftmost k characters; or the empty string at the end of sus if it has less than k characters. Raises Subscript if k < 0, even in the partial application triml(k).

[trimr k sus] returns sus less its rightmost k characters; or the empty string at the beginning of sus if it has less than k characters. Raises Subscript if k < 0, even in the partial application triml(k).

[sub (sus, k)] returns the k'th character of the substring; that is, i, n). Raises Subscript if k<0 or k>=n. s(i+k) where sus = (s,

[size (s, i, n)] returns the size of the substring, that is, n.

[slice (sus, i', NONE)] returns the substring (s, i+i', n-i'), where sus = (s, i, n). Raises Subscript if i' < 0 or i' > n.

[slice (sus, i', SOME n')] returns the substring (s, i+i', n'), where sus = (s, i, n). Raises Subscript if i' < 0 or n' < 0 or i'+n' > n.

[concat suss] returns a string consisting of the concatenation of the substrings. Equivalent to String.concat (List.map string suss). Raises Size if the resulting string would be longer than String.maxSize.

Raises [concatWith sep suss] returns a string consisting of the concatemation of the substrings in suss, using sep as a separator. Equivalent to String.concatWith sep (List.map string suss). Raise Size if the resulting string would be longer than String.maxSize.

[s(i), s(i+1), ..., s(i+n-1)]where sus = (s, i, n). Equivalent to String.explode(string ss). [explode sus] returns the list of characters of sus, that is,

[compare (sus1, sus2)] performs lexicographic comparison, using the standard ordering Char.compare on the characters. Returns LEBS, EQUAL, or GREATER, according as sus1 is less than, equal to, or greater than sus2. Equivalent to, but more efficient than, String.compare(string sus1, string sus2

using the [collate cmp (sus1, sus2)] performs lexicographic comparison, using given ordering cmp on characters. Equivalent to, but more efficient than, String.collate cmp (string sus1, string sus2).

(dropl p sus] drops the longest prefix (left substring) of sus all of whose characters satisfy predicate p. If all characters do, it returns the empty substring (s, i+n, 0) where sus = (s, i, n).

[dropr p sus] drops the longest suffix (right substring) of sus all of whose characters satisfy predicate p. If all characters do, it returns the empty substring (s, i, 0) where sus = (s, i, n).

[takel p sus] returns the longest prefix (left substring) of sus all of whose characters satisfy predicate p. That is, if the left-most character does not satisfy p, returns the empty (s, i, SUBSTRING

where sus = (s, i, n).

[taker p sus] returns the longest suffix (right substring) of suall of whose characters satisfy predicate p. That is, if the right-most character satisfies p, returns the empty (s, i+n, 0) where sus = (s, i, n).

Let p be a predicate and xxxxfyyyyfzzzz a string where all characters in xxxx and zzzz satisfy p, and f a is character not satisfying p. Then not satisfying p.

sus = XXXXXzzzzz			XXXXXZZZZZ	XXXXZZZZ
XXXXIYYYYIZZZZ	fyyyyfzzzz	xxxxfyyyyf	xxxx	ZZZZ
	"	П	П	П
II SIN	sns	sns	sns	sns
	Q	Д	Д	Ω
	dropl	dropr p sus	takel	taker p sus

concat[takel p sus, dropl p sus] = string sus concat[dropr p sus, taker p sus] = string sus It also holds that

[split] p sus] splits sus into a pair (sus1, sus2) of substrings where sus1 is the longest prefix (left substring) all of whose characters satisfy p, and sus2 is the rest. That is, sus2 begins with the leffmost character not satisfying p. Disregarding sideeffects, we have:

split1 p sus = (takel p sus, drop1 p sus).

[splitr p sus] splits sus into a pair (sus1, sus2) of substrings where sus2 is the longest suffix (right substring) all of whose characters satisfy p, and sus1 is the rest. That is, sus1 ends with the rightmost character not satisfying p. Disregarding sideeffects, we have:

splitr p sus = (dropr p sus, taker p sus)

[splitAt (sus, k)] returns the pair (sus1, sus2) of substrings, where sus1 contains the first k characters of sus, and sus2 contains the rest. Raises Subscript if k < 0 or k > size sus.

[isPrefix s1 s2] is true if s1 is a prefix of s2. That is, if there exists a string u such that s1 $^{\wedge}$ u = string s2.

[isSuffix s1 s2] is true if s1 is a suffix of s2. That is, if there exists a string t such that t ^ s1 = string s2.

[isSubstring of s2. That is, if there exist strings t and u such that t ^ s1 ^ u = strings t.

[position s (s',i,n)] splits the substring into a pair (pref, suff) of substrings, where suff is the longest suffix of (s', i, n) which has s as a prefix. More precisely, let m=size s. If there is a least index k in i.i+n-m for which s=s'(k..k+m-1), then the result is pref = (s', i, k-1) and suff = (s', k, n-(k-i)); otherwise the result is pref = (s', i, n) and suff = (s', i+n, 0).

[span (sus1, sus2)] returns a substring spanning from the start of sus1, the end of sus2, provided this is well-defined: sus1 and sus2 must have the same underlying string, and the start of sus1 must not be to the right of the end of sus2; otherwise raises Span.

More precisely, if base(sus1) = (s,i,n) and base(sus2) = (s',i',n') and s=s' and i <= i'+n', then base(join(sus1, sus2)) = (s,i,i'+n'-i). This may be used to compute 'span', 'union', and 'intersection'.

[translate f sus] applies f to every character of sus, from left to right, and returns the concatenation of the results. Raises Size if the sum of their sizes is greater than String.maxSize.

SUBSTRING 142

Equivalent to String.concat(List.map f (explode sus)).

[tokens p sus] returns the list of tokens in sus, from left to right, where a token is a non-empty maximal substring of sus not containing any delimiter, and a delimiter is a character satisfying p.

[fields p sus] returns the list of fields in sus, from left to right, where a field is a (possibly empty) maximal substring of sus not containing any delimiter, and a delimiter is a character satisfying p.

Two tokens may be separated by more than one delimiter, whereas two fields are separated by exactly one delimiter. If the only delimiter is the character #"", then "abc| |def contains three fields: "abc" and "def" abc| |def contains three fields: "abc" and "and "def"

[fold] f e sus] folds f over sus from left to right. That is, evaluates f(elim-1), f(...f(si[i]*l], f(s[i] *e)) ...)) tail-recursively, where sus = (s, i, n). Equivalent to List.fold] f e (explode sus).

[foldr f e sus] folds f over sus from right to left. That is, evaluates f(s[i), f(s[i+l]), f(...f(s[inn-1] % e) ...))) Equively, where sus = (s, i, n). Bqqivalet to List.foldr f e (explode sus).

[app f sus] applies f to all characters of sus, from left to right. Equivalent to List.app f (explode sus).

SUSP

Module Susp

Susp -- support for lazy evaluation

type 'a susp

-> 'a susp val delay: (unit -> 'a) -: val force: 'a susp -> 'a

[delay (fn () => e)] creates a suspension for the expression e. The first time the suspension is forced, the expression e will be evaluated, and the result stored in the suspension. All subsequent forcing of the suspension will just return this result, so e is evaluated at most once. If the suspension is never forced, then e is never evaluated.

['a susp] is the type of lazily evaluated expressions with result

type 'a.

[force su] forces the suspension su and returns the result of the expression $\ensuremath{\mathrm{e}}$ stored in the suspension.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                val
val
```

This structure provides input/output functions on text streams. The functions are state-based: reading from or writing to a stream changes the state of the stream. The streams are buffered: output to a stream may not immediately affect the underlying file or device.

[instream] is the type of state-based characters input streams

[outstream] is the type of state-based character output streams.

[elem] is the type char of characters.

[vector] is the type of character vectors, that is, strings.

TEXT INPUT:

[openIn s] creates a new instream associated with the file named s Raises Io.Io is file s does not exist or is not accessible. [closeIn istr] closes stream istr. Has no effect if istr is closed

TEXTIC

already. Further operations on istr will behave as if istr is at end of stream (that is, will return "" or NONE or true).

[input istr] reads some elements from istr, returning a vector \mathbf{v} of those elements. The vector will be empty (size $\mathbf{v}=0$) if and only if istr is at end of stream or is closed. May block (not return until data are available in the external world).

[inputAll istr] reads and returns the string v of all characters remaining in istr up to end of stream.

[inputNoBlock istr] returns SOME(v) if some elements v can be read without blocking; returns SOME("") if it can be determined without blocking that istr is at end of stream; returns NONE otherwise. If istr does not support non-blocking input, raises Isto.NonblockingNotSupported.

[input] istr] returns SOME(e) if at least one element e of istr is available; returns NONE if istr is at end of stream or is closed; blocks if necessary until one of these conditions holds.

[imputN(istr, n)] returns the next n characters from istr as a string, if that many are available; returns all remaining characters if end of stream is reached before n characters are available; blocks if necessary until one of these conditions holds. (This is the behaviour of the 'input' function prescribed in the 1990 Definition of Standard ML).

[inputLine istr] returns one line of text, including the terminating newline character. If end of stream is reached before a newline character, then the remaining part of the stream is returned, with a newline character added. If istr is at end of stream or is closed, then the empty string "" is returned.

[endOfStream istr] returns false if any elements are available in istr; returns true if istr is at end of stream or closed; blocks if necessary until one of these conditions holds.

[lookahead istr] returns SOME(e) where e is the next element in the stream; returns NONE if istr is at end of stream or is closed; blocks if necessary until one of these conditions holds. Does not advance the stream.

[stdIn] is the buffered state-based standard input stream.

[scanStream scan istr] turns the instream istr into a character source and applies the scanner 'scan' to that source. See StringCvt for more on character sources and scanners. The Moscow ML implementation currently can backtrack only 512 characters, and raises Fail if the scanner backtracks further than that.

TEXT OUTPUT:

[openOut s] creates a new outstream associated with the file named s. If file s does not exist, and the directory exists and is writable, then a new file is created. If file s exists, it is truncated (any existing contents are lost).

[openAppend s] creates a new outstream associated with the file named s. If file s does not exist, and the directory exists and is writable, then a new file is created. If file s exists, any existing contents are retained, and output goes at the end of the file.

[closeOut ostr] closes stream ostr; further operations on ostr (except for additional close operations) will raise exception Io.Io.

[output(ostr, v)] writes the string v on outstream ostr.

[output1(ostr, e)] writes the character e on outstream ostr.

TEXTIO 146

[flushOut ostr] flushes the outstream ostr, so that all data written to ostr becomes available to the underlying file or device.

[stdOut] is the buffered state-based standard output stream.

[stdErr] is the unbuffered state-based standard error stream. Ti is, it is always kept flushed, so flushOut(stdErr) is redundant.

[print s] outputs s to stdOut and flushes immediately.

The functions below are not yet implemented:

[setPosIn(istr, i)] sets istr to the (untranslated) position i. Raises Io.Io if not supported on istr.

[getPosIn istr] returns the (untranslated) current position of istr. Raises Io.Io if not supported on istr.

[endPosIn istr] returns the (untranslated) last position of istr. Because of translation, one cannot expect to read endPosIn istr - getPosIn istr from the current position.

[getPosOut ostr] returns the current position in stream ostr. Raises Io.Io if not supported on ostr.

[endPosOut ostr] returns the ending position in stream ostr. Raises Io.Io if not supported on ostr.

[setPosOut(ostr, i)] sets the current position in stream to ostr i. Raises Io.Io if not supported on ostr.

t

[mkInstream sistr] creates a state-based instream from the functional instream sistr.

[getInstream istr] returns the functional instream underlying the state-based instream istr.

[setInstream(istr, sistr)] redirects istr, so that subsequent input is taken from the functional instream sistr.

[mkOutstream sostr] creates a state-based outstream from the outstream sostr.

getOutstream ostr] returns the outstream underlying the

state-based outstream ostr.

[setOutstream(ostr, sostr)] redirects the outstream ostr so that subsequent output goes to sostr.

Module Time

TIME

val compare : time * time -> order

[time] is a type for representing durations as well as absolute points in time (which can be thought of as durations since some fixed time zero). Times can be negative, zero, or positive.

[zeroTime] represents the 0-second duration, and the origin of time, so zeroTime + t = t + zeroTime = t for all t.

[now ()] returns the point in time at which the application occurs. [fromSeconds s] returns the time value corresponding to s seconds.

[fromMilliseconds ms] returns the time value corresponding to ms milliseconds

[fromMicroseconds us] returns the time value corresponding to us microseconds [toSeconds t] returns the number of seconds represented by t, truncated (towards zero). Raises Overflow if that number is not representable as an int. [toMilliseconds t] returns the number of milliseconds represented by t, truncated (towards zero). Raises Overflow if that number is not representable as an int.

[toMicroseconds t] returns the number of microseconds represented by t, truncated (towards zero). Raises Overflow if t that number is not representable as an int.

[fromReal r] converts a real to a time value representing that many seconds. It holds that fromReal $0.0 = {\rm zeroTime}.$

[toReal t] converts a time to the number of seconds it represents; hence fromReal and toReal are inverses of each other.

TIME 148

[fmt n t] returns as a string the number of seconds represented by t, rounded to n decimal digits. If n <= 0, then no decimal digits t, rounded to are reported. [toString t] returns as a string the number of seconds represented by t, rounded to 3 decimal digits. Equivalent to (fmt 3 t).

[fromString s] returns SOME t where t is the time value represented by the string s of form $[\langle n \rangle t | *[+-2]?(([0-9]+(\backslash.[0-9]+)?)] (\langle.[0-9]+))$; or returns NONE if s cannot be parsed as a time value.

[scan getc src], where getc is a character accessor, returns SOME (t, rest) where t is a time and rest is rest of the input, or NONE if s cannot be parsed as a time value.

[+] adds two time values. For reals r1, r2 >= 0.0, it holds that fromReal r1 + fromReal r2 = fromReal(Real.+(r1,r2)). Raises Overflow if the result is not representable as a time value.

[-] subtracts a time value from another. That is, tl - t2 is the duration from t2 to tl (which may be negative). It holds that t - zeroTime = t.

[<] $[<+] \\ [<+] \\ [<+] \\ [>+] \\ [+] \\ [>+] \\ [+$

[compare(t1, t2)] returns LESS, EQUAL, or GREATER, according as tl precedes, equals, or follows t2 in time.

TIMER

Module Timer

Timer -- SML Basis Library

type real_timer type cpu_timer

: unit -> cpu_timer
: unit -> cpu_timer
: unit -> cpu_timer -> { usr : Time.time, sys : Time.time
: cpu_timer -> Time.time val startCPUTimer val totalCPUTimer val checkCPUTime val checkGCTime

val startRealTimer : unit -> real_timer
val totalRealTimer : unit -> real_timer
val checkRealTime : real_timer -> Time.time

[cpu_timer] is the type of timers for measuring CPU time consumption (user time, garbage collection time, and system time).

[real_timer] is the type of timers for measuring the passing of real time (wall-clock time).

[startCPUTimer ()] returns a cpu_timer started at the moment of the call.

[totalCPUTimer ()] returns a cpu_timer started at the moment the library was loaded.

[checkCPUTime tmr] returns {usr, sys} where usr is the amount of user CPU time consumed since tmr was started and sys is the amount of system CPU time consumed since tmr was started. Note that garbage collection time is included in the usr time. Under MS DOS and MS Windows, usr time is measured as real time.

as S [checkGCTime tmr] returns the amount of user CPU time spent garbage collection since tmr was started. Under MS DOS and Windows, gc time is measured in real time. [startRealTimer ()] returns a real_timer started at the moment of the call [totalRealTimer ()] returns a real_timer started at the moment the library was loaded.

[checkRealTime tmr] returns the amount of real time that has passed since tmr was started.

UNIX UNIX

Module Unix

```
Unix -- SML Basis Library
```

```
type proc
type signal = Signal.signal
val executeInEnv : string * string list -> proc
val execute
    : string * string list -> proc
val streamsOf : proc -> TextIO.instream * TextIO.outstream
val kill : proc * signal -> unit
val reap
val reap
```

This structure allows Moscow ML programs to start other processes and to communicate with them.

Child processes are not automatically terminated when the parent (MID) process terminates. To fortibly terminate a child process pr, use Unix kill (pr, Signal.term). Then, to remove the terminated process from the operating system tables, call Unix.reap(pr).

The protocol for communication between the ML program and its child process must be designed with some care, typically using non-blocking input for reading from the child process.

[proc] is the type of processes started by the ML program.

[signal] is the type of Unix-style signals, which can be sent to another process. Signal values must be obtained from the Signal structure.

execute (cmd, args)] asks the operating system to execute the command cmd with the argument list args, as a separate process. Two pipes connected to the standard input and standard output of the new process are created; these may be obtained using streamsOf. A proc value representing the new process is returned. The new process executes using the same environment as the calling process. Raises Fail in case of failure, e.g. if the process or the pipes cannot be created.

Typically, the cmd argument will be the full pathmame of an executable. On Unix systems, simple command searching as done by the shell, allowing cmd to be a relative pathname, can be achieved by using

execute("/bin/sh", "-c" :: concat (cmd :: " :: args))

[executeInEnv (emd, args, env)] asks the operating system to execute the command emd with the argument list args in the environment env, as a separate process. Returns a proc value representing the new process. Typically, a string in the env list has the form "NAME-VALUE". See also Process.getEnv.

[streamsOf pr] returns a pair (ins, outs) of input and output streams associated with process pr. The standard output of pr is the source for the input stream ins, and the standard input of pr is the sink for the output stream outs.

[reap pr] closes the input and output streams associated with pr, and then suspends the current (ML) process until the process corresponding to pr terminates. Returns the exit status given by pr when it terminated. Raises Fail in case of failure, e.g. if pr has already ben reaped.

Under Unix, information about a terminated process remains in the system tables until the process is reaped. Thus, an MI program using execute or executeInEnv must make sure to reap any process it has created, or else the system tables will fill up.

[kill (pr, s)] sends the signal s to the process pr. Raises Fail in case of failure, e.g. if pr has already been killed.

VECTOR

Module Vector

Vector -- SML Basis Library

type 'a vector = 'a vector

maxLen

```
option
                                                                                                                                                                                                                                                                                                                                                            order
                                                                                                                                                                                                                                                                                                             á á

```

['ty vector] is the type of one-dimensional, immutable, zero-based constant-time-access vectors with elements of type 'type 'ty vector admits equality if 'ty does. Vectors v1 and v2 are equal if they have the same length and their elements are equal.

[maxLen] is the maximal number of elements in a vector.

[fromList xs] returns a vector whose elements are those of xs. Raises Size if length xs > maxLen.

[tabulate(n, f)] returns a vector of length n whose elements are f 0, f 1, ..., f (n-1), created from left to right. Raises Size if n<0 or n>maxLen.

[length v] returns the number of elements in v.

[sub(v, i)] returns the i'th element of v, counting from 0. Raises Subscript if i<0 or i>=length v.

[update(v, i, x)] creates a copy of v, sets position i to x, and returns the new vector. In contrast to Array update, this is not a constant-time operation, because it must copy the entire vector. Raises Subscript if i<0 or i>=length v.

[concat vs] returns a vector which is the concatenation from left to right og the vectors in vs. Raises Size if the sum of the sizes of the vectors in vs is larger than maxLen.

[find p v] applies p to each element x of v, from left to right, until p(x) evaluates to true; returns SOME x if such an x exists otherwise NONE.

[exists p v] applies p to each element x of v, from left to right, until p(x) evaluates to true; returns true if such an x exists, otherwise false.

[all p v] applies p to each element x of v, from left to right, until p(x) evaluates to false; returns false if such an x exists, otherwise true.

VECTOR 152

```
[findi p a] applies f to successive pairs (j, a[j]) for j=0,1,...,n-1, until p(j, a[j]) evaluates to true; returns SOME (j, a[j]) if such a pair exists, otherwise NONE.
             That is,
                                                                                                                                                                                 That is,
                                                                                                                                                                                                                                                                                                                                                                                                                              [map f v] applies f to v[j] for j=0,1,...,length v-1 and returns a new vector containing the results.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      The following iterators generalize the above ones by passing also the vector element index j to the function being iterated.
[fold] f e v] folds function f over v from left to right. That i computes f(v[len-1], f(v[len-2], ..., f(v[l], f(v[0], e)) ...)), where len is the length of v.
                                                                                                                                                                       [foldr f e v] folds function f over v from right to left. computes f(v[0], f(v[1], ..., f(v[len-2], f(v[len-1], e)) where len is the length of v.
                                                                                                                                                                                                                                                                                                                                                         [app f v] applies f to v[j] for j=0,1,...,length v-1.
```

[foldli f e v] folds function f over the vector from left to right. That is, computes f(n-1, v[n-1], f(..., f(1, v[1], f(0, v[0], e)) ...)) where n = length v. [foldri f e v] folds function f over the vector from right to left. That is, computes f(0, v[0], f(1, v[1], ..., f(n-1, v[n-1], e) ...)) where n = length v. (appi f v] applies f to successive pairs (j, v[j]) for j=0,1,...,n-1 where n = length v.

[collate cmp (xs, ys)] returns LESS, EQUAL or GREATER according as xs precedes, equals or follows ys in the lexicographic ordering on vectors induced by the ordering cmp on elements. [mapi f v] applies f to successive pairs (j, v[j]) for $j=0,1,\dots,n-1$ where n = length v and returns a new vector containing the results.

['ty slice] is the type of vector slices, that is, sub-vectors. The slice (a.i,n) is valid if 0 < a : i = 1n < a size a; or equivalently, 0 < a : i and 0 < a : n and i : n < a size a. A valid slice sli = (a,i,n) represents the sub-vector a[i...i+n-1], so the elements of sli are a[i], a[i+1], ..., a[i+n-1], and n is the length of the slice. Only valid slices can be constructed by the functions below.

[length sli] returns the number n of elements in sli = (s,i,n).

[sub (sli, k)] returns the k'th element of the slice, that is, a(i+k) where sli = (a,i,n). Raises Subscript if k<0 or k>=n.

[slice (a, i, NONE)] creates the slice (a, i, length a-i), consisting of the tail of a starting at i.
Raises Subscript if i<0 or i > Vector.length a. Equivalent to slice (a, i, SOME(Vector.length a - i)).

[slice (a, i, SOME n)] creates the slice (a, i, n), consisting of the sub-vector of a with length n starting at i. Raises Subscript if i<0 or n<0 or i+n > Vector.length a.

	a[0len-1]	a[0n-1]	a[ilen-1]	a[ii+n-1]
meaning	the whole vector	a left sub-vector (prefix)	a right sub-vector (suffix)	a general slice
slice	(a, 0, NONE)	(a, 0, SOME n)	(a, i, NONE)	(a, i, SOME n)

[full a] creates the slice (a, 0, Vector.length a). Equivalent to slice(a,0,NONE)

[subslice (sli, i', NONE)] returns the slice (a, i+i', n-i') when sli = (a,i,n). Raises Subscript if i' < 0 or i' > n.

[subslice (sli, i', SOME n')] returns the slice (a, i+i', n') when sli = (a,i,n). Raises Subscript if i' < 0 or n' < 0 or i'+n' > n.

VECTORSLICE 154

'n [base sli] is the concrete triple (a, i, n) when sli = (a, i,

[vector sli] creates and returns a vector consisting of the elements of the slice, that is, a[i..i+n-1] when sli = (a,i,n).

concat slis] creates a vector containing the concatenation of slices in slis.

sli = (a,i,n) is empty isEmpty sli] returns true if the slice that is, if n=0. LILEM sli] returns SOME(x, rst) where x is the first element and the remainder of sli, if sli is non-empty; otherwise returns getItem

to each element x of sli, from left to mates to true; returns SOME x if such an [find p sli] applies p to earight, until p(x) evaluates exists, otherwise NONE. [exists p sli] applies p to each element x of sli, from left to right, until p(x) evaluates to true; returns true if such an x exists, otherwise false.

p sli] applies p to each element x of sli, from left to right, l p(x) evaluates to false; returns false if such an x exists, otherwise true.

sli] applies f to all elements of sli = (a,i,n), from o right. That is, applies f to a[j+i] for j=0,1,...,n. [app f sli] app left to right. p f sli] applies f to all elements of sli = $(a,i,n)\,,$ from left right, and returns a vector of the results. [map f

[fold] f e sli] folds function f over sli = (a,i,n) from left to right. That is, computes f(a[i+n-1], f(a[i+n-2],..., f(a[i+1], f(a[i], e))...)).

[foldr f e sli] folds function f over sli = (a,i,n) from right to left. That is, computes f(a[i], f(a[i+1],..., f(a[i+n-2], f(a[i+n-1], e))...)).

following iterators generalize the above ones by also passing index into the vector a underlying the slice to the function The following it the index into t being iterated.

[findi p sli] applies p to the elements of sli = (a,i,n) and the underlying vector indices, and returns the least (i,a[j]) for which p(i), a[j]) evaluates to true, if any; otherwise returns NONE. That is, evaluates p(j,a[j]) for j=i,...+n-1 until it evaluates to true for some j, then returns SOME(j,a[j]); otherwise returns NONE.

[appi f sli] applies f to the slice sli = (a,i,n) and the underlying vector indices. That is, applies f to successive pairs (j,a[j]) for $j=i,i+1,\ldots,i+n-1$.

[mapi f sli] applies f to the slice sli = (a,i,n) and the
muderlying vector indices, and returns a vector of the results.
That is, applies f to successive pairs (i, a[j]) for
j=i,i+i,...,i+n-i, and returns #[f(i,a[i]), ..., f(i+n-1,a[i+n-1])].

[foldli f e sli] folds function f over the slice sli = (a,i,n) and the underlying vector indices from left to right. That is, computes f(i+n-1, a[i+n-1], f(..., f(i+1, a[i+1], f(i, a[i], e)) ...)).

[foldri f e sli] folds function f over the slice sli = (a,i,n) and the underlying vector indices from right to left. That is, computes f(i, a[i], f(i+1, a[i+1], ..., f(i+n-1, a[i+n-1], e) ...)).

[collate cmp (sli1, sli2)] returns LESS, EQUAL or GREATER according as sli1 precedes, equals or follows sli2 in the lexicographic ordering on slices induced by the ordering cmp on elements.

['a weak] is the type of weak pointers to objects of type 'a. A weak pointer is a pointer that cannot itself keep an object alive. Hence the object pointed to by a weak pointer may be deallocated by the garbage collector if the object is reachable only by weak pointers. In this case, subsequent accesses via the 'get' function will raise Fail 'Dangling weak pointer. (We raise an exception instead of returning an option value, because access via a weak pointer to a deallocated object is likely to be a programming

error).

Integers, characters, words and booleans will not be deallocated by the garbage collector and will remain reachable forever by a weak pointer. Reals, strings, tuples and other non-nullary constructors may be deallocated by the garbage collector. Compile-time constants, even composite ones, will not be deallocated either.

[weak v] creates and returns a weak pointer to value v.

[get w] returns the value pointed to by weak pointer w, if the value is still alive. Otherwise raises Fail "Dangling weak pointer".

[set(w, v)] makes the weak pointer w point to the value v.

[isweak w] returns true if the value pointed to by w is dead; returns false otherwise. If an object is reported to be dead, it remains dead. However, an object is reported to be live just if it has not yet been deallocated by the garbage collector. The allocation of any new value may activate the garbage collector and cause the object to die. Thus if not (isweak w) then get w else "blah" will not raise exception Fall, whereas the following might: if not lisweak w) then (1.2) @ [3.4]; get w) else "blah" because evaluation of the list append may cause w to die.

The value of isweak w is the same as that of

WEAK 156

vyet w; false) handle Fail => true
but evaluating the latter expression may have the side effect of
keeping w alive for slightly longer, because a pointer to w is
returned by get w.

['a array] is the type of arrays of weak pointers to objects of type 'a. A value of type 'a Weak.weak (above) is equivalent to, but more efficient than, a one-element 'a Weak.array. On the other hand, an 'a Weak.array is more efficient than an ('a Weak.weak) Array.array.

[array n] creates an array of n weak pointers. Initially, any access to the array will raise Fail.

[sub(a, i)] returns the object pointed to by cell i (counting from 0) of the array a, if it is live. Raises Fail "Dangling weak pointer" if cell i has never been updated or if the object pointed to has been deallocated by the garbage collector. Raises Subscript if i<0 or i>=length a. To make 'sub' infix, use the declaration infix 9 sub

[update(a, i, v)] updates cell i of array a to point (weakly) to the value v. Raises Subscript if i<0 or i>=length a.

[isdead(a, i)] returns true if the object in cell i of array a is dead, and false otherwise. Analogous to isweak; see above

[length a] returns the number of elements in a.

[maxLen] is the maximal number of elements in an array.

The iterators described below operate on the live elements only. Note that an element alk] may die in the course of folding f over earlier elements (e.g. a[1] ... a[k-1]). Thus the functions should be used with great care.

[fold] f e a] folds function f over the live elements of a, from left to right [folds f e a] folds function f over the live elements of a, from right to left.

[app f a] applies f to the live elements of a from left to right

[modify f a] applies f to a[j] and updates a[j] with the result f(a[j]), for each live element a[j], from left to right.

The following iterators generalize the above ones in two ways:

the index j is also being passed to the function being iterated; the iterators work on a slice (subarray) of an array.

is, The slice (a, i, SOME n) denotes the subarray a[i..i+n-1]. That is a[i] is the first element of the slice, and n is the length of the slice. Valid only if 0 <= i <= i + n <= length a. The slice (a, i, NONE) denotes the subarray a[i..length a-1]. That is, the slice denotes the suffix of the array starting at i. Valid only if 0 <= i <= length a. Equivalent to (a, i, SOME(length a - i)).

	ay a[0len-1] a[0n-1] a[0n-1] ray (suffix) a[ilen-1]	1)
meanitig	naa t	a generar
	(a, 0, NONE) (a, 0, SOME n) (a, i, NONE)	COLUMN II
1 U	(a, 0, (a, i,	(a, t)

[foldli f e (a, i, SOME n)] folds function f over the live elements of the subarray a[i..i+n-1] from left to right. Raises Subscript

if i<0 or n<0 or i+n > length a.

WEAK

[foldli f e (a, i, NONE)] folds function f over the live elements of the subarray a[i..len-1] from left to right, where len = length a. Raises Subscript if i<0 or i > length a.

[foldri f e (a, i, SOME n)] folds function f over the live elements of the subarray a[i..i+n-1] from right to left. Raises Subscript of the subarray all...... if i<0 or n<0 or i+n > length a.

[foldrif e (a, i, NONE)] folds function f over the live elements of the subarray a[i..len-1] from right to left, where len = length a. Raises Subscript if i<0 or i > length a.

[appi f (a, i, SOME n)] applies f to successive pairs (j, a[j]) for j=i,i+1,...,i+n-1, provided a[j] is live. Raises Subscript if i<0 or n<0 or i+n > length a.

[modifyi f (a, i, SOME n)] applies f to (j, a[j]) and updates a[j] with the result f(j, a[j]) for j=i,i+1,...,i+n-1, provided a[j] is live. Raises Subscript if i<0 or n<0 or i+n > length a. [appi f (a, i, NONE)] applies f to successive pairs (j, a[j]) for j=i,i+1,...,len-1, where len = length a, provided a[j] is live. Raises Subscript if i<0 or i > length a.

13 [modifyi f (a, i, NONE)] applies f to (j, a[j]) and updates a[j] with the result f(j, a[j]) for j=i,i+1,...,len-1, provided a[j] ilive. Raises Subscript if i<0 or i > length a.

[word] is the type of n-bit words, or n-bit unsigned integers.

[wordSize] is the value of n above. In Moscow ML, n=31 on 32-bit machines and n=63 on 64-bit machines.

[orb(w1, w2)] returns the bitwise 'or' of w1 and w2.

[andb(w1, w2)] returns the bitwise 'and' of w1 and w2.

[xorb(w1, w2)] returns the bitwise 'exclusive or' or w1 and w2.

[notb w] returns the bitwise negation (one's complement) of w.

 $[\ \ \ \ \ \ \]$ returns the arithmetic negation (two's complement) of w.

 $[<<(w,\ k)]$ returns the word resulting from shifting w left by k bits. The bits shifted in are zero, so this is a logical shift. Consequently, the result is 0-bits when k >= wordSize.

[>>(w, k)] returns the word resulting from shifting w right by k

WORD

bits. The bits shifted in are zero, so this is a logical shift. Consequently, the result is 0-bits when $k \to \infty dSize$.

[->>(w, k)] returns the word resulting from shifting w right by k bits. The bits shifted in are replications of the left-most bit: the sign bit', so this is an arithmetical shift. Consequently, for k >= wordSize and wordToInt w >= 0 the result is all 0-bits, and for k >= wordSize and wordToInt w <= 0 the result is all 1-bits.

To make <<, >>, and ~>> infix, use the declaration infix 5 << >> ~>>

: : : : :

[mod] represent unsigned integer addition, subtraction, multiplication, division, and remainder, modulus 2 raised to the n'th power, where n-wordSize. The operations (i div j) and (i mod j) raise Div when j=0. Otherwise no exceptions are raised.

>=] compare words as unsigned integers.

[compare(w1, w2)] returns LESS, EQUAL, or GREATER, according as w1 is less than, equal to, or greater than w2 (as unsigned integers).

[min(w1, w2)] returns the smaller of w1 and w2 (as unsigned integers).

[max(w1, w2)] returns the larger of w1 and w2 (as unsigned integers).

[fmt radix w] returns a string representing w, in the radix (base) specified by radix.

output format		[01]+	+[0-1]+	+[6-0]	[0-9A-F]+
	-	2	8	10)	16)
		(base	(base	(base	(base
no.		l binary	octal	decimal	hexadecimal
description		unsigned	unsigned	unsigned	unsigned
radix		BIN	OCT	DEC	HEX

[toString w] returns a string representing w in unsigned hexadecimal format. Equivalent to (fmt HEX w).

[fromString s] returns SOWE(w) if a hexadecimal unsigned numeral can be scanned from a prefix of string s, ignoring any initial whitespace; returns NONE otherwise. Raises Overflow if the scanned number cannot be represented as a word. An unsigned hexadecimal numeral must have form, after possible initial whitespace: [0-9a-fA-F]+

[scan radix getc charsrc] attempts to scan an unsigned numeral from the character source charsrc, using the accessor getc, and ignoring any initial whitespace. The radix argument specifies the base of the numeral [NIN, OCT, DEC, HEX). If successful, it returns SOME(w, rest) where w is the value of the numeral scanned, and rest is the numead part of the character source. Raises Overflow if the have form, after possible initial whitespace:

input format	 (0w)?[0-1]+	(0m)?[0-7]+	(0M)?[0-9]+	(0wx 0wX 0x 0X)? $[0-9a-fA-F]$
radix	 BIN	OCT	DEC	HEX

[coInt w] returns the (signed) integer represented by bit-pattern w. [toIntX w] returns the (signed) integer represented by bit-pattern w. [fromInt i] returns the word representing integer i.

WORD160

[tolargeInt w] returns the (signed) integer represented by bit-pattern w. [tolargeIntX w] returns the (signed) integer represented by bit-pattern w. [fromLargeInt i] returns the word representing integer i.

[toLargeWord w] returns w. [toLargeWordX w] returns w. [fromLargeWord w] returns w.

radix		BIN	OCT	DEC	HEX

[toString w] returns a string representing w in unsigned hexadecimal format. Equivalent to (fmt ${\tt HEX}$ w).

[fromString s] returns SOME(w) if a hexadecimal unsigned numeral can be scanned from a prefix of string s, ignoring any initial whitespace: returns NONE otherwise. Raises Overflow if the scanned number cannot be represented as a word. An unsigned hexadecimal numeral must have form, after possible initial whitespace:

[scan radix {getc} charsrc] attempts to scan an unsigned numeral from the character source charsrc, using the accessor getc, and ignoring any initial whitespace. The radix argument specifies the base of the numeral (BIN, OCT, DEC, HEX). If successful, it returns SOME(w, rest) where w is the value of the numeral scanned, and rest is the unused part of the character source. Raises Overflow if the scanned number cannot be represented as a word. A numeral must have form, after possible initial whitespace:

radix input format

BIN (0W)?[0-1]+

CCT (0W)?[0-7]+

DEC (0W)?[0-9]+

HEX (0WC][0X][0X]?[0-9a-fA-F]+

[toInt w] returns the integer in the range 0..255 represented by w.

[toIntX w] returns the signed integer (in the range ~128..127)

WORD8

represented by bit-pattern w.

[fromInt i] returns the word holding the 8 least significant bits of i.

[toLargeInt w] returns the integer in the range 0..255 represented by w

[toLargeIntX w] returns the signed integer (in the range ~128..127 represented by bit-pattern w.

[fromLargeInt i] returns the word holding the 8 least significant bits of i.

[toLargeWord w] returns the Word.word value corresponding to w.

[toLargeWordX w] returns the Word.word value corresponding to w, with sign extension. That is, the 8 least significant bits of the result are those of w, and the remaining bits are all equal to the most significant bit of w: its 'sign bit'.

[fromLargeWord w] returns w modulo 256

[array] is the type of one-dimensional, mutable, zero-based constant-time-access arrays with elements of type Word8, word, that is, 8-bit words. Arrays al and a2 are equal if both were created by the same call to a primitive (array0, array, tabulate, fromList).

All operations are as for Array.array.

WORD8ARRAYSLICE

Module Word8ArraySlice

```
: (int * elem -> bool) -> slice -> (int * elem) option

: (int * elem -> unit) -> slice -> unit

[slice] is the type of WordBArray slices, that is, sub-arrays of WordBArray, array values.

The slice (a,i,n) is valued if 0 <= i <= i +n <= size s. or equivalently, 0 <= i and 0 <= n and i+n <= size s. Avalid slice sli = (a,i,n) represents the sub-array a[i...i+n-1], so the elements of sli are a[i], a[i+l], ..., a[i+n-1], and n is the length of the slice. Only valid slices can be constructed by the functions below.

All operations are as for ArraySlice.slice.

```

[vector] is the type of one-dimensional, immutable, zero-based constant-time-access vectors with elements of type Word8.word, that is, 8-bit words. Type vector admits equality, and vectors v1 and v2 are equal if they have the same length and their elements are equal.

All operations are as for Vector.vector.

WORD8VECTORSLICE

[slice] is the type of Word8Vector slices, that is, sub-vectors of Word8Vector.vector values.

The slice (a,i,n) is valid if 0 <= i <= i +n <= size s.

The valid slice sli = (a,i,n) represents the sub-vector a[i...i+n-1], so the elements of sli are a[i], a[i+1], ..., a[i+n-1], and n is the length of the slice. Only valid slices can be constructed by these functions.

All operations are as for VectorSlice.slice.
